If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring, filing the broken end to a sharp, square edge and using it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material.

Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston* as the brush will round off the edges of the ring lands. Pistons showing scuffed or scored skirts should be scrapped. Examine the ring lands carefully for cracks. If the piston is in the least bit doubtful, it should be discarded.

PISTON RINGS

V6 and V8

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the body by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS

V6 and V8

Piston pins are a pressed fit in the upper end of the connecting rod and a slide fit in the piston bosses.

ROD BEARINGS

V6 and V8

Connecting rod bearings are of the precision insert type and if worn can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves. The clearance between the rod bearing and the crankshaft can be measured by the use of Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall cap and tighten the bolts to the torque listed in the *Engine Tightening Data* table.
4. Remove bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage envelope. The number within the graduation on the envelope indicates the clearance in thousandths of an inch, Fig. 12.

Fig. 13 Tool for removing upper main bearing shells

MAIN BEARINGS

V6 and V8

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearing with .005" to .015" cardboard. (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out, Fig. 13.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening Data* table.

CRANKSHAFT OIL SEAL

V6 and V8

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool, Fig. 14. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible

Fig. 14 Rear main bearing oil seals

to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN

V6 and V8

1. Raise car and drain oil.
2. Disconnect exhaust pipe at crossover.
3. If equipped with manual shift transmission, loosen clutch equalizer-to-frame bolts.
4. Remove steering idler arm bracket-to-suspension crossmember bolts.
5. Support engine either with a jack or with chains around the exhaust manifold.
6. Remove bolts and nuts attaching engine mounts to mount brackets.
7. Raise engine and insert bolts through bracket bolt holes, then lower engine so mounts rest on bolts.
8. Remove lower flywheel housing.
9. Remove oil pan bolts and lower pan enough to remove oil pump pipe and screen-to-cylinder block bolts.
10. Rotate crankshaft to provide maximum clearance at forward end of oil pan. Move front of pan to the right and lower pan through opening between crossmember and steering linkage intermediate shaft.

OIL PUMP

V6 and V8

The oil pump is located in the timing chain cover where it is connected to a drilled passage in the crankcase to an oil screen housing and pipe assembly.

1. To remove the oil pump cover and gears, first remove the oil filter.
2. Disconnect wire from oil pressure indicator switch in filter by-pass valve cap, Fig. 15.
3. Remove screws attaching oil pump cover assemly to timing chain cover.
4. Remove cover assembly and slide out oil pump gears.

Inspection

1. Wash all gears and replace any not found serviceable.
2. Disassemble oil pump cover.
3. Check relief valve for wear or scoring. Check the relief valve spring to see that it is not worn on its side or collapsed. Thoroughly clean the screen staked in the relief valve bore of the cover.
4. Check the valve in its bore in the cover. The valve should have no more clearance than an easy slip fit. If any perceptible side shake can be felt the valve and/or cover should be replaced.
5. Check filter by-pass valve for cracks, nicks or warping. The valve should be flat and free of nicks or scratches.

Assembly & Installation

1. Lubricate and install valve parts in cover, Fig. 15. Install caps and torque to 30-35 ft. lbs.
2. Install gears and shaft in oil pump body section of timing chain cover and check gear end clearance.
3. Place straightedge over gears and measure clearance between straightedge and gasket surface. Clearance should be .0018" to .0058". If clearance is less than .0018", check timing chain cover gear pocket for evidence of wear.
4. Remove gears and pack gear pocket full of vaseline (not chassis lube). Reinstall gears so vaseline is forced into every cavity of the gear pocket and between the gear teeth. Place new gasket in position. *Unless the pump is packed as directed, it may not prime itself when the engine is started.*
5. Install cover screws and torque them to 10-15 ft. lbs. Then install oil filter.

RADIATOR

To remove the radiator, drain cooling system and disconnect all hose. Remove attaching bolts and brackets and remove radiator.

Fig. 15 Oil Pump cover and related parts

Fig. 16 Water pump

WATER PUMP, REPLACE

V6 and V8

1. Drain cooling system.
2. Remove fan and pulley or pulleys from pump shaft.
3. Disconnect hose from pump.
4. Unfasten and remove pump from timing chain cover.

WATER PUMP REPAIRS

V6 and V8

The water pump cover is die cast aluminum into which the water pump bearing outer race is shrunk fit. For this reason the cover, shaft bearing and hub are not replaceable. The shaft seal and impeller are the only replaceable parts of the pump, Fig. 16. To replace these parts, proceed as follows:

1. Pull impeller from shaft.
2. Remove carbon washer, pump bellows and spring from brass sleeve that is pressed into the pump housing. It is not necessary to remove the sleeve if it is in good condition. However, if it is necessary, drive the sleeve out with a punch inserted through the vent hole in pump body.
3. Clean pump cover to remove scale, etc. Do not use cleaning solvent as it may leak into bearings and destroy the lubricant.
4. If old brass seal sleeve was removed, carefully press new seal assembly into body using a thick walled tube of suitable diameter.
5. If old sleeve was not removed, separate new sleeve from bellows by soaking in hot water to soften cement used to hold seal parts together for ease of handling. Install carbon washer bellows and spring in old sleeve, being careful to engage notches of washer with driving dents of brass sleeve.
6. Coat face of carbon washer and impeller hub with rust preventative; then press impeller on shaft until rear face of impeller hub is flush with end of shaft. *Pump must be*

Fig. 17 V8 ignition details

Fig. 18 V6 ignition details

supported on forward end of shaft only while pressing on impeller.

DISTRIBUTOR, REPLACE

V6 and V8

1. Disconnect primary wire from coil and hose from vacuum unit.
2. Remove distributor cap by inserting a screwdriver in upper slotted end of cap latches; then press down and turn 90° counterclockwise.
3. Make a mark on distributor housing in line with the center of the rotor. Then carefully note the direction the vacuum unit points in relation to the engine so that the distributor can be replaced in the exact same position. *If engine is turned over while distributor is out, complete ignition timing procedure must be followed.*
4. Remove distributor clamp and lift distributor out of timing chain cover.
5. Reverse removal procedure to install the distributor and leave the clamp bolt just loose enough to permit movement of the distributor for ignition timing, Figs. 17 and 18.

IGNITION TIMING

V6 and V8

Correct ignition timing exists when the yellow timing mark on the vibration damper is aligned with the "5" mark on the timing indicator with engine running at slow idle and with No. 1 piston up on its compression stroke.

STARTER, REPLACE

V6 and V8

To remove the starter, disconnect battery cable from battery. Disconnect cable and solenoid lead wire from solenoid switch. Remove starter attaching bolts and take off starter.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Rochester 2GC carburetor for V8 engine

Rochester 2GC carburetor for V6 engine

Rochester 4GC carburetor

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Rochester 4GC carburetor exterior linkage

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

Fig. ①—2GC float level.

ROCHESTER NOTES

Fig. ②—2GC float drop.

Fig. ③—With throttle valves fully closed, bend pump rod as necessary to obtain dimension specified from top of pump housing to top of pump rod.

Fig. ④—Bend unloader tang on throttle lever to obtain clearance specified between upper edge of choke valve and inner wall of air horn with throttle valves wide open.

Fig. ⑤—Fast idle adjustment is not required if hot idle speed is correctly set and choke rod properly adjusted. To adjust choke rod, turn idle stop screw 1½ turns against fast idle cam with choke valve fully open. Place idle stop screw on second step on fast idle cam against shoulder of high step. There should be the clearance specified between upper edge of choke valve and wall of air horn. Bend tang to adjust.

ROCHESTER NOTES
continued

⑥—With engine at normal operating temperature, open throttle to clear fast idle cam and rotate cam to extreme fast idle position; then allow throttle to close against fast idle cam. Adjust dashpot until it just touches throttle lever. With transmission in Drive and brakes applied, jab accelerator pedal and release rapidly. If engine stalls from too rapid closing of throttle, move dashpot toward throttle lever until its action prevents engine stalling. If excessive time is required for throttle to reach fully closed position, move dashpot away from throttle lever. If proper control cannot be obtained by adjustment, replace dashpot.

Fig. ⑦—4GC fast idle adjustment

Fig. ⑨—4GC secondary float level

Fig. ⑩—4GC primary float drop

Fig. ⑪—4GC secondary float drop

Fig. ⑫—4GC pump rod adjustment

Fig. ⑬—4GC unloader adjustment

⑭—Close throttle so that fast idle screw contacts second highest step of fast idle cam with side of screw against rise to high step of cam. Then check clearance between choke valve and air horn dividing wall with gauge size listed. If clearance is not correct, bend choke rod as required.

Clutch & Synchromesh Transmission Section

Fig. 1 Synchromesh transmission shift controls. 1961-62

CLUTCH PEDAL, ADJUST

Free play of the clutch pedal should be ⅞″ to 1″ when the pedal is depressed by hand. Insufficient pedal free play will cause the clutch release bearing to ride against the clutch release levers all the time, resulting in abnormal wear of these parts. It may also cause clutch slippage and abnormal wear of the driven plate, flywheel and pressure plate if pressure on release levers is enough to prevent positive engagement of the clutch. To adjust the pedal free play, proceed as follows:

Pull outer end of clutch fork rearward until clutch release bearing contacts clutch release levers. Free movement at the outer end of the fork should be approximately 3/16″.

If free movement of fork is not 3/16″, remove clevis pin from rear end of clutch release rod and rotate rod as required to make free movement correct. Reinstall clevis pin and check to see that free pedal play is correct.

CLUTCH, REPLACE

1. Remove transmission as described further on.
2. Remove flywheel lower cover.
3. Remove clutch release bearing.
4. Disconnect release rod from fork.
5. Unhook fork boot from opening in flywheel housing.
6. Push inward on release fork to free it from ball stud in flywheel housing and remove fork through bottom of housing.
7. Mark clutch cover and flywheel with a center punch so that cover can be reinstalled in same position on flywheel in order to preserve engine balance.
8. Loosen each clutch cover bolt a turn at a time in order to relieve clutch spring pressure evenly and thereby avoid distortion of cover. Metal spacers (such as ¼″ nuts) placed between release levers and inner edge of cover will aid removal and later reinstallation by holding clutch springs partially compressed.
9. Support pressure plate and clutch cover assembly while removing last bolts, then remove clutch cover and driven plate.
10. Reverse removal procedure to install the clutch and adjust free pedal play as outlined previously.

Clutch, Overhaul

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment.

SHIFT CONTROLS, ADJUST

Need for shift control adjustment is indicated if either the lower control shaft lever contacts the edge of the steering column jacket opening, or if the manual control lever does not move smoothly from the 2nd-3rd range to the 1st-reverse range when the lever is lifted straight toward the steering wheel. If an adjustment is indicated, refer to Fig. 1.

TRANSMISSION, REPLACE

1. If transmission is to be disassembled, drain the lubricant. Fill with kerosene and run transmission in neutral for 15 seconds; then drain.
2. Mark front universal joint and front companion flange so that these parts can be reassembled in the same relative position.
3. Remove two U-bolts attaching U-joint to companion flange and slide propeller shaft rearward as far as possible for working clearance.
4. Disconnect shift linkage from transmission.
5. Disconnect speedometer cable.
6. Loosen all three exhaust pipe ball joints so that transmission and rear end of engine can be lowered.
7. Remove two bolts attaching transmission mounting pad to support. Leave mounting pad bolted to transmission.
8. Place a flat wood block on jack and jack under engine pan until transmission mounting pad clears transmission support.
9. Remove transmission support (4 bolts).
10. Lower jack so that transmission will clear underbody during removal.
11. Remove upper left and lower right transmission mounting bolts and install guide pins in these bolt holes.
12. Remove other two bolts and slide transmission straight back until drive gear shaft is free of clutch housing; then lower transmission.
13. Reverse removal procedure to install transmission.

TRANSMISSION REPAIRS

Disassembly

1. Referring to Fig. 2, remove top cover.
2. Remove front bearing retainer.
3. Remove retainer holding speedometer sleeve in rear bearing retainer, and remove driven gear and sleeve.
4. Remove companion flange from rear of transmission.
5. Remove rear bearing retainer.
6. Remove speedometer drive gear.
7. Drive countershaft-idler shaft lock plate from ends of shafts.
8. Drive countershaft rearward with a brass drift until shaft is just free in front shaft bore of case.
9. Using a suitable dummy shaft to hold bearings and thrust washers intact, allow countershaft to drop to bottom of case.
10. Remove main drive gear and bearing, and 14 pilot rollers from rear end of shaft.
11. Remove front bronze blocking ring from synchronizer. Remove snap ring from front of mainshaft.
12. Move mainshaft rearward until rear bearing is free of case. Then move

Fig. 2 Synchromesh transmission exploded. 1961-62

mainshaft to extreme right of case, which will permit the 2nd-3rd shift fork to be removed.

13. Remove mainshaft by sliding shaft rearward through rear of case, at the same time stripping mainshaft as shaft is being withdrawn.
14. Remove 1st-reverse shift shoe from shift shaft. Drive reverse idler shaft out of case using a brass drift. Lift out reverse idler gear.
15. Lift cluster gear assembly from case.

Reassembly

During reassembly, apply a thin film of transmission lube to all parts. Always use new seals and gaskets. Refer to Fig. 2 and assemble the transmission in the following sequence:

Countershaft Assembly

1. Install dummy shaft or Loading Tool J-8965 in cluster gear.
2. Insert tubular spacer.
3. Hold cluster gear in vertical position and while supporting loading tool from below, insert inner bearing spacer (washer) and place 22 rollers around loading tool, using heavy grease to hold them in place. Insert outer bearing spacer. Then insert rollers on opposite end.
4. Install inner rear bronze thrust washer so that lugs engage notches in cluster gear. Install outer rear steel thrust washer. Large front thrust washer should not be installed at this time.

Synchronizer Assembly

1. Install springs solidly in recesses on both ends of synchronizer hub. One end of both springs should be located in same shift plate slot so that springs will extend in opposite directions from each other. Install shift plate directly over these ends.
2. While holding shift plates in their grooves, slide synchronizer sleeve over hub until detent is felt. The extended tapered portion of the sleeve faces the same direction (front) as the long extended portion at the center of the hub.
3. Place rear blocking ring in position at rear end of hub and rotate until shifting plates match notches in blocking ring. Blocking ring remains free until assembly of transmission.

Shift Levers & Interlock

Insert new seals and apply transmission lube in seals and shaft holes. Then install shift levers, interlock and related parts as indicated in Fig. 2.

When assembled, shift 2nd-3rd shift lever into 2nd speed position. With one end of interlock sleeve against 1st-reverse cam, the clearance between sleeve and 2nd-3rd cam should be .001-.007". If clearance is greater than specified, and if it seems possible that the transmission can be forced into two gears at once, the old interlock sleeve should be measured with a micrometer and replaced with a new, longer sleeve. Sleeves are available in five lengths: 1.287", 1.291", 1.295", 1.299" and 1.303".

Mainshaft & Main Drive Gear

1. Locate slinger washer on drive gear shaft with raised center portion toward front. Press bearing on shaft with outer snap ring groove toward front. Install bearing outer snap ring and thickest shaft snap ring that will properly seat in snap ring groove (three thicknesses are available).
2. Press bearing on rear of mainshaft with outer snap ring groove toward rear. Install bearing outer snap ring and shaft snap ring.
3. With bearing loading tool in place, and with cluster gear parts in place except front thrust washer, lower cluster gear assembly vertically through top of case with rear section of gear down. Then position cluster gear in horizontal position to allow front of cluster gear to pass projections in transmission case.
4. Locate cluster gear in normal position with lug on outer rear thrust washer up, and move loading tool rearward about ¼" to pass into bore of case. Insert large front thrust washer with lug to front so as to en-

Fig. 3 Optional four-speed synchromesh transmission. See Chevrolet chapter for service procedure

gage slot in case. Align hole in washer with bore in cluster gear and move loading tool forward allowing cluster gear to drop to bottom of case.

5. End play of cluster gear should be .005″ to .017″ measured between two rear thrust washers. If clearance is excessive, replace thrust washers.
6. Locate reverse idler gear with hub section and chamfered side of teeth forward. Drive reverse idler shaft in through rear of case with lock plate slot toward countershaft bore. Leave shaft projecting about $\frac{1}{16}$″ from fully installed position.
7. Insert 1st-reverse shift shoe in its shift shaft and install mainshaft and bearing through rear of case. As shaft is being installed, slide 1st-reverse gear on shaft with groove on gear toward front. Slide 2nd speed gear on shaft with extended portion toward front. With rear blocking ring in position, slide synchronizer on shaft with extended portion of sleeve toward front. Install mainshaft snap ring. Insert 2nd-3rd shift fork in its shaft and engage fork in grove in synchronizer sleeve. With 1st-reverse shoe offset toward front, engage shift shoe in groove on its gear. Move complete mainshaft assembly forward until rear bearing is fully installed in case bore.
8. With synchronizer hub and 2nd speed gear pressed forward against snap ring, there should be .003″ to .016″ end clearance between 2nd gear and front facing of 1st-reverse gear splines. Replace worn parts if clearance is excessive.
9. Place front blocking ring at front end of synchronizer hub and rotate until shift plates match notches in blocking ring.
10. Insert 14 pilot rollers in drive gear pocket, holding them in place with heavy grease.
11. Install drive gear and bearing through front of case, sliding bearing rollers in rear end of drive gear over front end of mainshaft.
12. Check clearance between front blocking ring teeth and drive gear teeth by lightly seating blocking ring on contacting surface of gear. Minimum clearance should be .045″. If less replace blocking ring.
13. Turn transmission upside down to allow cluster gear assembly to drop to normal position. Align holes in case with cluster gear and drive out loading tool by installing countershaft. Leave countershaft projecting about 1/16″ from fully installed position.
14. Install lock plate in slots of countershaft and reverse idler shaft. Then drive both shafts forward until lock plate is tight against the case.
15. Install front bearing retainer and gasket, being sure oil return hole in retainer and gasket match oil hole in case.
16. Complete the assembly by installing rear bearing retainer seal, speedometer drive gear, companion flange, speedometer driven gear and sleeve with new O-ring, and driven gear retainer.
17. Install top cover with new gasket and check transmission in all shift positions.

FOUR SPEED TRANS.

Fig. 3 shows an exploded view of the four-speed synchromesh transmission furnished as optional equipment. For repairs on this unit see the *Chevrolet* chapter.

Automatic Transmission Section

DESCRIPTION

This transmission, Fig. 1, provides five different control or operating ranges which may be manually selected by the driver through movement of the control lever. Letters on the stationary dial on the control panel identify each range as follows: P for parking; N for neutral; D for drive; L for low, and R for reverse.

The transmssion case is bolted to the engine crankcase through the converter housing section of the case. The transmission case, converter housing and rear bearing retainer are one integral cast aluminum part.

The torque converter is coupled to the engine and transmits engine torque hydraulically to a planetary gear set, the planet gear carrier of which is splined to the output shaft. The torque converter, of course, provides torque multiplication to meet varying driving conditions.

The converter clutch, when engaged, transmits approximately 36% of the engine torque to the planetary gear set

Fig. 2 Manual control and throttle linkage adjustments. 1961-62

Fig. 1 Sectional view of automatic transmission. 1961-62

front sun gear. Thus part of the engine torque is transmitted mechanically to the output shaft.

The forward clutch is a multiple disc clutch which, when engaged, locks the cam of the stator and rear sun gear overrunning clutches to the transmission case. The forward clutch is engaged in Low and Drive Ranges to allow the stator and rear sun gear to turn in one direction only (with the engine).

The coast clutch is a multiple disc clutch which, when engaged, locks the rear sun gear to the cam of the stator and rear sun gear overrunning clutches. The coast clutch also locks the overrunning clutch cam to part of the forward clutch discs. Thus, when both the coast clutch and forward clutch are engaged, the rear sun gear and overrunning clutch cam are locked to the transmission case. The coast clutch is engaged in all ranges except Drive.

The reverse clutch is a multiple disc clutch which, when engaged, locks the turbine and planet set ring gear to the transmission case. The reverse clutch, of course, is engaged in Reverse range.

Overrunning clutches. The rear of the stator and rear sun gear shafts are splined to overrunning clutch races. The clutches are arranged to allow rotation with respect to the clutch cam in one direction only (with the engine).

The hydraulic control system includes devices for controlling engagement of the disc clutches, filling the torque converter and circulation of oil for lubrication and heat transfer.

MAINTENANCE

Adding Oil

Check transmission oil level with transmission oil warm, transmission in Park and engine idling. Remove the oil level dipstick, wipe dry with a clean cloth and reinstall to full depth. Remove dipstick and note level.

If oil level is below "ADD" mark on dipstick, add automatic transmission oil as required but do not fill above the "FULL" mark. The distance between the "FULL" and "ADD" marks represents approximately one pint.

Changing Oil

At 25,000 mile intervals, the transmission oil pan should be removed and cleaned. The oil strainer should be replaced and fresh oil added to the transmission. *This operation should not be attempted unless accurate foot pound and inch pound torque wrenches are available and the operator is fully qualified in their use.*

1. Remove bolt and seal attaching oil pan to transmission.
2. Remove oil pan and case seal.
3. Remove oil strainer and 0-ring seal.
4. Install new strainer and 0-ring seal. Torque strainer strap bolts to exactly 100 inch pounds. Do not overtighten.
5. Clean oil pan. Install new seal on pan using care not to stretch seal.
6. Install oil pan and seal, oil pan bolt and bolt seal. Torque oil pan bolt to 15-20 ft. lbs. Do not overtighten.
7. Add two quarts of oil to transmission. Start engine and allow to idle in Park range. Then add oil to bring level to the "FULL" mark on dipstick with transmission warmed up.

LINKAGE, ADJUST

Throttle Linkage

1. Referring to Fig. 2, hold throttle rod in wide open position (against stop on carburetor.)
2. Hold idler lever in full throttle valve position (through detent to stop). *Do not confuse detent position of throttle valve with stop position. Increased resistance will be felt as the throttle valve reaches detent position. The idler lever should be pushed through detent to stop.*
3. Adjust turnbuckle so no lost motion exists in slide link (wide open throttle and throttle valve stop reached simultaneously).
4. Tighten lock nut on turnbuckle.

Manual Linkage

1. Referring to Fig. 2, loosen adjusting swivel clamp bolt.
2. Set transmission selector lever in neutral detent.
3. Move shift lever against neutral stop.
4. Tighten adjusting swivel clamp nut.

TROUBLE SHOOTING

With linkage properly adjusted and engine warmed up, make a road test and observe general performance of transmission and check for abnormal noises. Accelerate from a stop with accelerator depressed just to detent. Upshift should occur smoothly between 40 and 45 mph. If upshift occurs at speeds other than those specified, refer to text below for possible causes.

Uphift At Too Low Speed

1. Governor valve not adjusted properly or sticking.
2. Shift valve or shift valve regulator sticking.
3. Throttle valve pressure too low—worn or broken spring or valve sticking.

Upshift At Too High Speed

1. Governor valve not adjusted properly or sticking.
2. Shift valve and shift valve regulator sticking.

Slow Engagement of Converter Clutch

1. Converter pressure regulator valve sticking, lowering converter pressure too slow.

Fast Engagement Of Converter Clutch

1. Converter charging pressure too low.
2. Converter pressure regulator valve sticking.

TRANSMISSION, REPLACE

1. Raise car and support front and rear.
2. Remove exhaust crossover pipe.
3. Remove front U-joint bolts and slide propeller shaft rearward to separate U-joint at transmission. Support propeller shaft to avoid weight of shaft damaging center U-joint.
4. Place suitable jack under transmission and fasten jack to transmission.
5. Remove transmission crossmember.
6. Disconnect speedometer cable.
7. Loosen shift linkage swivel clamp nut (see Fig. 2). Remove cotter pin, spring and washer attaching equalizer to range selector outer lever and remove equalizer.
8. Remove oil filler pipe.
9. Support engine at oil pan.
10. Remove transmission cover pan.
11. Mark flywheel and converter pump for reassembly in same position and remove three converter-to-flywheel bolts.
12. Remove transmission-to-engine bolts.
13. Move transmission rearward to provide clearance between converter pump and crankshaft.
14. Lower transmission out of car. *Wire converter to transmission case or otherwise suitably retain it. If not retained, converter will fall out if transmission is tilted forward even slightly.*
15. Reverse removal procedure to install the transmission.

TRANSMISSION REPAIRS

Converter & Gear Set

Disassembly

1. Remove converter-to-housing bolts.
2. Provide a pail to catch oil as it drains from converter.
3. Pry converter pump away from housing using screwdriver in slots provided.
4. Remove converter pump and clutch.
5. Remove front sun gear, thrust bearing and two select fit thrust bearing races.
6. Slide planet carrier out of ring gear.
7. Separate front and rear tanged thrust washers from front planet unit.
8. Remove rear sun gear and thrust bearing.
9. Lift out stator and turbine.
10. Remove converter pump housing.
11. Remove rear sun gear and thrust bearing.
12. Lift ring gear from turbine shaft after removing three bolts.
13. Lift stator and thrust bearing from turbine.
14. Lift turbine and thrust bearing from pump cover.

Inspection of Parts

1. Examine tanged thrust washers for scoring or wear.
2. Check all gears for scoring, imbedded metal or looseness on shafts. Worn or loose pinions require replacement of carrier assembly. Pick out imbedded metal with small screwdriver.

3. Check babbitted surfaces of rear sun gear, turbine and stator shafts. If babbitt is chipped or flaked off, effected part must be replaced.
4. Check needle thrust bearings for looseness or wear.
5. Check stator and turbine for chipped, cracked or broken vanes.
6. Examine converter pump housing for scoring, burrs or roughness that might damage pump seal or pump bushing when re-installed.

Reassembly—Follow the step-by-step procedure shown in Figs. 3 through 12.

Fig. 3 Place turbine and needle thrust bearing in pump housing

Fig. 4 Set stator and needle thrust bearing in turbine

Fig. 5 Set ring gear in turbine. Bolt holes are unevenly spaced so ring gear may be installed in only one position. Torque ring gear bolts to 15-20 ft. lbs.

Fig. 6 Set sun gear and needle thrust bearing in place

Fig. 7 Install tanged thrust washers in front and rear of planet carrier. Tangs on washers must engage notches in carrier

Fig. 8 Set carrier with tanged washers in place on rear sun gear. Deep side of carrier toward rear sun gear

Fig. 9 Set front sun gear in place on planet carrier

Fig. 10 Set needle thrust bearing and two select fit bearing races on top of front sun gear

Fig. 11 Place converter clearance gauge in place as shown. Loosen thumb screw and push plunger down to bear on needle thrust bearing and races. Tighten thumb screw

Fig. 12 Turn gauge over and set on converter pump. Assemble dial indicator with indicator bearing on plunger. Zero indicator. Loosen thumb screw and observe indicator reading. If, when gauge is set in place, plunger holds gauge up so legs do not rest on pump rim, indicator reading when thumb screw is released will be in compression, not clearance. If plunger drops when thumb screw is released, indicator reading will be in clearance, not compression. Select needle thrust bearing races to provide .010" clearance to .005" compression

Converter Clutch & Converter Pump

Disassembly

1. Pry converter clutch housing retainer ring out of groove in converter pump.
2. Lift converter clutch housing out of pump.
3. Remove converter clutch pack.
4. Remove converter clutch piston and apply plate using pliers.
5. Unhook, expand and remove converter clutch piston inner ring.
6. Remove converter clutch outer piston ring.

Inspection of Parts

1. Examine clutch plate contact surface for wear or scoring.
2. Examine clutch plates for scoring, warping or excessive wear.
3. Examine apply plate for excessive wear.
4. Check piston bore in converter pump for scoring or pitting. Check inner bore of piston for wear or scoring.
5. Check clutch piston inner ring for wear or scoring.
6. Examine clutch outer piston ring for excessive wear.
7. Examine converter pump for chipped, cracked or broken vanes. Check for damaged or loose pump ring.

Reassembly—Follow step by-step procedure shown in Fig. 13 through 20.

Fig. 13 Expand and install clutch inner piston ring and hook ends

Fig. 14 - Place clutch outer piston ring squarely in lower part of bore (about 1/4" from bottom). Ring gap must be .002-.007". If less than .002" file end of ring; if more than .010" replace ring

Fig. 15 Install outer piston ring on clutch piston and apply plate

Fig. 16 Lubricate liberally and push piston and apply plate into bore of converter pump. A chamfer in bore serves to compress outer piston ring; however, if difficulty is encountered, a thin feeler gauge may be used to start ring ends over chamfer

Fig. 17 When new, clutch friction plates are .079-.084" thick. Plates worn thinner than .074" should be replaced. All separator plates must be installed with "dish" same way. Starting with a friction plate, then a separator plate, continue alternating plates, being sure to lubricate each friction plate as plates are installed

Fig. 18 Rotate piston apply plate so tangs of apply plate are centered in openings

Fig. 19 Lower clutch housing and clutch pack into converter pump. Retain clutch plates with fingers until assembly is properly aligned. Long tangs of housing must engage openings in converter pump

Fig. 20 Install housing retaining ring over clutch housing in groove of converter pump. Tap ring solidly into groove with drift

Front Pump

Disassembly

1. Remove pump bolts and grasp pump body with pliers and hand and lift pump clear of case.

2. Lift pump out of case. Reverse clutch hub will usually be removed with pump. A tanged thrust washer may remain on top of stator overrunning clutch race. It should be placed in rear of reverse clutch hub.
3. Use air pressure applied to reverse clutch piston apply hole to remove reverse clutch piston from clutch housing. Cover assembly with cloth to protect against oil spatter.
4. Examine clutch piston outer seal for damage; if necessary to replace, remove seal.
5. Upon inspection, if necessary to replace clutch piston inner seal, remove seal.
6. Remove and discard oil pump body-to-case seal.
7. Remove reverse clutch piston housing-to-pump body bolts.
8. Lift clutch piston housing off pump, lifting straight up to avoid damage to dowel pin holes. Slipper sealing pins may stick to reverse clutch piston housing and be removed with housing.

Inspection of Parts

1. Mount a dial indicator and zero indicator on pump body.
2. Move indicator plunger to bear on pump slippers one at a time. Slippers should be .001" to .0028" below surface of pump body.
3. Move indicator plunger to rest on rotor. Check rotor in several places. Rotor should be .001" to .0028" below pump body.
4. Examine bushing; if worn or scored, remove rotor, slippers, springs and pins and drive out bushing and seal with a suitable driver. Install new bushing. Apply Permatex to outer diameter of new seal and install seal.
5. Examine rotor, slippers, springs and pins for wear, scoring or pitting.

Reassembly

1. Install rotors with driving tangs "up", Fig. 21. Install slippers and springs.
2. Install sealing pins, Fig. 22. Lubricate assembly liberally with automatic transmission oil.
3. Set reverse clutch piston housing squarely in place on pump body. Dowel pins are unevenly spaced so assembly is possible in only one position.
4. Install reverse clutch piston housing-to-pump body bolts and torque alternately and evenly to 15-20 ft. lbs.
5. Install new oil pump body-to-transmission case sealing ring.
6. Install reverse clutch piston inner seal with lip toward front of piston.
7. Install reverse clutch piston outer seal with lip toward front of piston.
8. Lubricate seals and install piston in piston housing, using a loop of smooth wire to start lips of seals into bore, Fig. 23. Inner seal lip should be started first. A satisfactory tool can be made by crimping a loop of .020" music wire in a short length of copper tube.

Transmission Clutches

Disassemble Reverse Clutch

1. Remove lever assembly ring and apply levers.
2. Lift out reverse clutch hub, thrust washer on front side and tanged washer on rear.
3. Remove reverse clutch hub oil ring and thrust washer.
4. Remove bellville release spring.
5. Remove pressure plate.
6. Remove reverse clutch pack.

Fig. 21 Install rotor, slippers and springs

Fig. 22 Install sealing pins

Fig. 23 Installing reverse clutch piston

Remove Coast, Overrunning & Forward Clutches

1. Remove forward and reverse clutch anchor.
2. Rotate forward and reverse clutch backing plate to disengage lugs from slots in case. Remove backing plate.
3. Grasp overrunning clutch cam and roller retainer and lift out complete set of clutches.
4. Lift forward clutch pack off coast clutch housing.
5. Remove forward clutch pressure plate.
6. Pry forward clutch release spring retaining ring out of groove in case.
7. Remove bellville forward clutch release spring.
8. Remove forward clutch apply levers.

Disassemble Coast & Overrunning Clutches

1. Use a suitable compressing tool to bear against coast clutch cylinder and pry ring out of groove in housing.
2. Lift coast clutch piston and cylinder out of housing.
3. Use pliers to remove piston from cylinder.
4. Remove piston outer seal if damaged.
5. Remove piston inner seal if damaged.
6. Remove coast clutch hub-to-support thrust washer.
7. Remove coast clutch apply levers.
8. Remove coast clutch release spring.
9. Remove coast clutch pressure plate.
10. Tip coast clutch housing to remove clutch pack and hub.
11. Pry cam retaining ring out of groove in backing plate.
12. Tilt coast clutch housing to remove backing plate and overrunning clutch.
13. Pull rear sun gear race out of cam assembly. Rollers and springs will fall out.
14. Remove roller thrust washer.
15. Pull stator race out of cam. Rollers and springs will fall out.

Inspection of Parts

1. Check apply levers for wear or bending.
2. Examine clutch hub oil rings for wear.
3. Examine thrust washers and tanged washers for wear.
4. Check bellville springs for cracks or wear.
5. Examine pressure plates for wear.
6. When new, friction plates are .079" to .084" thick. Plates worn thinner than .074" should be replaced.

Fig. 24 Place stator race inside cam and assemble rollers and springs. Stator race has larger splined I.D. than rear sun gear race

Fig. 25 Lubricate and install thrust washer on stator race

Fig. 26 Set rear sun gear cam in place on thrust washer and assemble rollers and springs

Fig. 27 Install cam and race in coast clutch housing. Rotate cam so lugs on cam engage notches in coast clutch housing

Fig. 28 Set assembly on blocks or otherwise support lower edge of coast clutch housing. Then install coast clutch backing plate on cam and race

Fig. 29 Install retaining ring solidly in groove of coast clutch housing above backing plate

Fig. 30 Install coast clutch hub on rear sun gear race

Fig. 31 Lubricate coast clutch friction plate and install on backing plate with splines engaged with coast clutch hub splines

Fig. 32 All separator plates must be installed with "dish" same way. Alternately install friction plate, then separator plate and so on until all plates are installed, being sure all friction plates have been oiled

Fig. 33 Install pressure plate on top of last lubed friction plate. Engage lugs in notches of coast clutch housing

Assemble Coast & Overrunning Clutches

1. Follow procedure given in Figs. 24 through 33, then complete the assembly as follows:
2. Install bellville clutch release spring on pressure plate with inner edge of spring "up".
3. Install apply levers with concave edge "in" between lugs of pressure plate and flat on release spring. Apply a daub of chassis lube on each lever to hold in place.
4. Set thrust washer in place on top of coast clutch hub.
5. Install piston inner seal with lip toward rear of piston.
6. Install piston outer seal with lip toward rear of piston.
7. Lubricate seals and install piston in bore of coast clutch cylinder by using a loop of smooth wire to start lips of seals in bore. Start inner seal first.
8. Make sure thrust washer and all apply levers are properly in place. Then install cylinder and piston assembly squarely in bore of coast clutch housing.
9. Apply pressure to coast clutch cylinder so that the retaining ring can be installed in groove of coast clutch housing.

10. Insert rear sun gear in sun gear race. Turn sun gear clockwise to check for drag on coast clutch. Excessive drag will indicate clutch separator plates all not dished same way, or foreign material is present. Sun gear overrunning clutch should not permit rotation in the counterclockwise direction.

Assemble Reverse Clutch—This procedure is included with the installation of the front oil pump further on.

Valve Body

Removal

1. Remove oil pan.
2. Remove oil strainer strap bolts. Remove strap, strainer and O-ring seal.
3. Use needle nose pliers to remove parking lock pawl disengaging spring.
4. Remove remaining valve body bolts and valve body. Take care when removing valve body as some of the valves can fall out.

Disassemble—Use Fig. 34 as a guide when disassembling valve body. When disassembled, test each valve in its bore. All valves must move freely of their own weight.

Reassemble

1. Referring to Fig. 34, begin the assembly by installing the converter pressure regulator, shift and main line pressure regulator valves, sleeves and springs. Use new valve retaining plate-to-valve body gasket; install plate and oil gauge guide. Install and tighten screws.
2. Install throttle pressure regulator valve. Tilt valve body so valve slides to bottom of bore.
3. Being sure throttle pressure regulator valve is in bottom of bore, install throttle pressure valve stop; be sure it is in the correct opening.
4. Install second stage governor valve.
5. Install second stage governor valve spring, sleeve and retainer. Press in on sleeve against spring pressure and install retainer through valve body in wide slot of sleeve.
6. Install check ball.
7. Install detent poppet and spring.
8. Use new gaskets, one on each side of valve body plate and position plate and gaskets on valve body. *It will be necessary to depress detent poppet to allow plate attaching screws to be started.*
9. Make sure detent poppet is properly in place and install screws (do not overtighten).
10. Install throttle detent valve and throttle pressure regulator valve spring.
11. Install range selector valve, governor valve and pin. *It may be necessary to shake valve body to start governor valve pin through hole in second stage governor valve.*

Coast Clutch Support & Forward Clutch Piston

Removal

1. Remove companion flange and pull three adapter sleeves and retainer out of transmission case and coast clutch support.
2. Pull output shaft forward to remove shaft, coast clutch support, parking lock ratchet wheel and governor as an assembly.
3. Slide governor lever actuating sleeve, needle thrust bearing, bearing race and parking lock ratchet wheel spacer off rear of output shaft.
4. Slide governor weight and retainer assembly off rear of output shaft.
5. Slide coast clutch support and forward clutch piston off forward end of output shaft.

Inspection

1. Discard any questionable O-ring seals.
2. Examine needle thrust bearing, race and sleeve for wear or scoring.
3. Check roll pins for looseness in governor weights.
4. If the two hooked oil rings on output shaft are worn or scored, unhook, expand and remove the rings.
5. If parking lock ratchet wheel is worn or broken, expand and remove retaining ring on output shaft forward of wheel. Slide wheel off shaft and examine output shaft for damaged splines, scored bearing surfaces, broken ring lands. etc.

Disassembly

1. Cover assembly with clean cloth as a protection against oil spatter and apply compressed air into center oil transfer sleeve hole to remove forward clutch piston from coast clutch support.
2. Examine hooked oil rings, forward clutch piston outer and inner seals and remove these parts if damage is evident.

Reassembly—Follow procedure shown in Figs. 35 through 41. Fig. 42 illustrates the removal and installation of governor lever and pin.

Fig. 35 Install and hook ends of oil rings on coast clutch support

Fig. 34 Exploded view of valve body

Fig. 36 Install piston outer seal with lip of seal toward rear of piston

Fig. 37 Install piston inner seal with lip of seal toward rear of piston

Fig. 41 Lubricate needle thrust bearing and slide spacer, sleeve, needle thrust bearing and race on rear of output shaft. Position against governor weights

Fig. 44 Install and tighten screw and nut

Fig. 38 Lubricate seals and install forward clutch piston. A loop of .020" music wire may be used as an aid in starting seal lip into piston bore. Start inner seal lip first

Fig. 42 If governor lever is damaged or pin hole is badly worn, remove pin retaining plug in side of transmission case. Slide pin out of case and lever. Install pin through lever and case and install plug

Fig. 45 Assemble special washer and O-ring on throttle control lever shaft. Lube O-ring and slide shaft onto range selector shaft

Fig. 39 Lubricate oil rings and slide coast clutch support and forward clutch piston on output shaft

Fig. 43 Install and lube O-ring seal. Slide shaft through case and carefully align splines on shaft with splines in inner lever. Hold outer lever and shaft "in" against case and push inner lever completely on shaft

Fig. 40 Slide governor weight retainer and weight assembly on rear of output shaft. Inner tangs of retainer must be inside openings of parking lock ratchet wheel. Forward end of weights must also be inside openings of wheel

Fig. 46 Carefully engage splines on shaft with splines in inner lever. Press lever on shaft completely. Install and tighten clutch head screw and nut

Range Selector Levers & Shaft

If these parts are removed, make the installation as shown in Fig. 43 to 46.

Transmission, Assemble

Follow the procedure shown in the illustrations starting with Fig. 47 to 84.

Fig. 47 Lube coast clutch support O.D. and position support so oil transfer holes are "up". Hold governor in place against parking lock wheel and start rear of shaft through bearing. Ease assembly into position. If parking lock pawl is installed, hold it "up" out of the way to allow assembly to move fully into case. If necessary to rotate support to line up oil transfer holes, insert a smooth punch through oil transfer holes in case to rotate support

Fig. 48 Lube and install oil transfer sleeves, O-rings and retainers. Retainers should be positioned flat against sleeves. Lube liberally with chassis lube to avoid damage to seal and install speedometer drive gear on output shaft. Install companion flange

Fig. 49 Install forward clutch apply levers

Fig. 50 Install forward clutch release spring flat on levers (inner edge of spring down)

Fig. 51 Install release spring retainer solidly in groove of case. Center spring as necessary to install ring fully into groove. Be very certain that ring is in groove all the way around

Fig. 52 Set forward clutch pressure plate on apply levers. Be sure to position wide space between lugs toward top of case for installation of anchor later

Fig. 53 Set coast and overrunning clutch assembly on coast clutch support

Fig. 54 Check forward clutch separator plate (no notches on lugs) for "dish". Note direction of dish and install it on forward clutch pressure plate. Be sure to position wide space between lugs toward top of case for installation of anchor later. Lube a forward clutch friction plate with automatic transmission oil. Install over coast clutch housing by engaging splines of plate with splines on coast clutch housing. Continue alternately installing a separator plate and a lubed friction plate until five separator plates (all dished same way) and five friction plates have been installed. All separator plates must be installed with wide space between lugs toward top of case for installation of anchor later

Fig. 55 Install forward and reverse clutch backing plate on top of forward clutch pack. Rotate backing plate so its lugs engage lugs in case. Correct installation of forward clutch pack will provide sufficient clearance and require no force to install backing plate

Fig. 56 Install forward and reverse clutch anchor in slot at top of case

Fig. 57 Be sure tanged thrust washer is in place at rear of reverse clutch hub

Fig. 58 Set reverse clutch hub in place on overrunning clutch

Fig. 59 Lubricate and install reverse clutch friction plate on forward and reverse clutch backing plate by engaging splines on hub with splines on plate

Fig. 60 Check reverse clutch separator plate (notch in tangs) for "dish". Note direction of dish and install separator plate above friction plate. Install plate with wide space between lugs toward top of transmission to clear anchor. Continue the build-up of clutch by alternately installing a lubed friction plate and a separator plate until four friction plates and three separator plates have been installed. All separator plates must be installed with dish same way

Fig. 61 Reverse clutch pressure plates are supplied in two thicknesses. If new pressure plate is being installed, measure an old plate in an unworn area near the end of a lug. A new plate to be installed must be the same thickness or reverse clutch pack clearance will be adversely affected. Install pressure plate over top friction plate with wide space between lugs toward top of transmission to clear anchor

Fig. 62 Install reverse spring and assembling ring over pressure plate with center edge of release spring "up". Do not install apply levers until hub clearance has been checked and thrust washer between reverse clutch hub and reverse clutch piston housing has been selected

Fig. 63 Set gauge shown on oil pump-reverse piston housing with gauge bearing firmly on center hub of reverse clutch piston housing. Loosen thumb screw and allow plunger to bear on gasket surface of oil pump. Tighten thumb screw

Fig. 64 Install new pump gasket over 5/16" guide pins in case. Place a select fit thrust washer on hub. Set gauge over reverse clutch hub with ends of gauge resting squarely on gasket. Check clearance between end of plunger and select fit thrust washer with .006" and .035" feeler gauges. If .006" gauge will not fit, select one size thinner washer. If the .035" feeler will fit, select one size thicker washer

Fig. 65 Install reverse clutch apply levers in notches of pressure plate, flat on release spring and with lever ends under assembling ring. Push assembling ring down on levers to hold them in place. Chassis lube daubed on levers will help keep them in place. It is not necessary to remove guide pins and gasket for this operation

Fig. 66 Liberally lube thrust washer and oil pump body-to-case seal. Carefully line up bolt holes with guide pins and lower pump into place. Install and tighten at least three oil pump-to-case bolts

Fig. 67 Insert a .029" feeler gauge through case between reverse clutch friction plate and a separator plate. A .029" feeler should "go" and a .051" feeler should "not go". If pack clearance is less than .030", it may be due to an incorrect pressure plate, separator plates not dished same way or apply levers incorrectly installed and binding on piston. If pack clearance is more than .050", it may be due to incorrect pressure plate or excessively worn friction or separator plates. If reverse clutch pack is satisfactory, remove guide pins, install remaining special bolts and captive sealing lock washers. Torque alternately and evenly to 20-24 ft. lbs.

Fig. 68 Set valve body in place on case and engage pin of range selector inner lever with groove of selector valve. Install parking lock pawl disengaging spring. Install bolts as shown

Fig. 69 Torque bolts in sequence shown to 100 inch pounds

Fig. 70 Insert a .025" feeler between forward edge of rear land of governor valve and sleeve. Hold governor lever rearward and valve forward against feeler. Adjust screw so it just touches end of valve with valve held in against feeler. Remove feeler

Fig. 71 Install new O-ring on oil strainer and set strainer in place on valve body

Fig. 72 Install strainer strap

Fig. 73 Torque bolts indicated to 100 inch pounds in sequence shown. If removed, install parking lock pawl. Install oil pan and torque the single pan bolt to 15-20 ft. lbs.

Fig. 74 Set tool shown over output shaft. Tool centers converter pump housing so housing hub does not damage seal during installation. Lube hub of pump housing and install carefully. Rotate housing to engage lugs on pump with slots of pump housing hub. Remove tool.

Fig. 75 Use chassis lube to retain caged needle thrust bearing to rear of turbine as shown. Oil exit holes to rear

Fig. 78 Lube sun gear shaft inside and out. Slide sun gear and needle thrust bearing into place. Rotate gear to engage splines. Two sets of splines must be engaged (sun gear race and coast clutch hub). Do not force gear as damage to splines will result

Fig. 81 Lube and assemble needle thrust bearing and two select fit bearing races into front sun gear. Retain with chassis lube

Fig. 76 Set stator and turbine in pump housing. Rotate turbine and stator to engage splines. Assembly will drop into place when splines are lined up

Fig. 79 Set planet carrier over rear sun gear with tanged thrust washers in place front and rear. Deeper pocket of carrier "down" toward rear sun gear and splined portion "up"

Fig. 82 Engage splines on sun gear hub with splines of converter clutch friction plates. Rotate gear while pressing down very lightly until all splines are engaged

Fig. 77 Assemble caged needle thrust bearing to rear of rear sun gear. Oil exit holes to rear

Fig. 80 Assemble new converter pump oil seal to pump. Seal is square section and must not be twisted

Fig. 83 Hold front sun gear in place with long screwdriver while positioning converter pump against pump housing. Rotate assembly very slightly to mesh front sun gear with planet pinions. When gears are in mesh, push converter pump into converter pump housing and pull housing toward pump

Fig. 84 Before installing attaching bolts, check locating hole through housing and matching hole part way through converter pump flange. These holes must line up to preserve balance of assembly. Set transmission vertical. Install and tighten special nuts and bolts alternately and evenly. Torque to 15-20 ft. lbs. Wire or otherwise retain converter to case prior to installation in car

Rear Axle & Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

As shown in Fig. 1, the drive pinion is mounted on two tapered roller bearings that are preloaded by two selected spacers. The drive pinion is positioned by shims located between a shoulder on the pinion and the rear bearing. The front bearing is held in place by a large nut.

The differential is supported in the carrier by two tapered roller side bearings. These are preloaded by inserting shims between the bearings and the pedestals. The differential assembly is positioned for ring gear and pinion backlash by varying these shims.

Axle Shaft, Replace

1. To remove the axle shafts, Fig. 1, take off the wheels. *Note that the left side wheel bolts have left hand threads and the nuts are marked "LH".*
2. Remove brake drums.
3. Remove nuts holding retainer plates to brake backing plates. Pull retainers clear of bolts and reinstall two lower nuts finger tight to hold brake backing plate in position.
4. Pull out axle shafts using a puller and adapter with a slide hammer. *While pulling axle shaft out through oil seal, support shaft carefully in center of seal to avoid cutting seal lip.*
5. Reverse removal procedure to install axle shafts. Note that the left shaft is shorter than the right shaft. Apply wheel bearing grease in the bearing recesses of the housing. Install new outer retainer gaskets. Insert axle shaft carefully until shaft splines engage in differential to avoid damage to seals. Torque retainer stud nuts to 60 ft. lbs.

Propeller shaft and universal joints

Axle Shaft Bearing

1. With axle shaft removed, nick bearing retainer in three or four places with a chisel deep enough to spread ring. Retainer will then slip off.
2. Press bearing off shaft. An arbor press may be used.
3. Press new axle shaft bearing against shoulder on axle shaft. *Retainer plate which retains bearing in housing must be on axle shaft before bearing is installed; retainer gasket can be installed after bearing.*
4. Press new retainer ring against bearing.

Axle Shaft Seal

1. Insert axle shaft so that splined end is just through seal.
2. Using axle shaft as a lever, push down on shaft until seal is pried from housing.
3. Apply sealer to O.D. of new seal.
4. Position seal over a suitable installer and drive seal straight into axle housing until fully seated.

Rear Axle Repairs

Disassembly and assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash and other differential case operations are given in the *Rear Axles Chapter*. The following operations are significant for this type rear axle.

Side Bearing Preload

After the differential case has been

Fig. 1 Rear axle assembly

assembled, differential side bearing preload is adjusted by changing the thickness of both the right and left shim by an equal amount. By changing the thickness of both shims equally, the original backlash will be maintained. Differential adjustment shims are available in thicknesses ranging from .040″ to .082″ in .002″ increments.

In order to adjust side bearing preload accurately, adjustment should be made before the pinion is installed. This allows the ring gear and case assembly to be rotated freely.

Place differential case and bearing assembly in carrier. If new side bearings are installed, use original adjusting shims; if same bearings are to be reused, select new right and left adjusting shims each .002″ thicker than the original shim. Slip right shim in position at right bearing, then drive left shim carefully into position using a soft hammer.

Rotate differential case several complete turns to seat bearings. Check bearing preload with an inch-pound torque wrench applied to a ring gear attaching bolt. With torque wrench projecting approximately straight out, bearing preload should read 20-30 inch lbs. with new bearings and 10-20 inch lbs. with reused bearings. If preload is not within these limits, increase shim thickness .002″ on each side for each added 10 inch lbs. preload desired, or decrease shim thickness .002″ on each side for each 10 inch lbs. preload to be subtracted.

When adjustment is satisfactory, remove differential, keeping bearing caps and shims together so that they may be reinstalled properly after the drive pinion has been installed.

Drive Pinion Preload

If new pinion bearings are installed, use the original pinion preload spacers. If the same bearings are being reused, select a pair of pinion preload spacers having a total thickness of .002″ less than the original spacers. Install spacers on pinion and position pinion in carrier. Pinion preload spacers are furnished to be used in pairs so that the possible combined thickness ranges from .400″ to .470″.

Install pinion and bearings and new oil seal. Install flange and nut, torquing nut to 200 ft. lbs. Rotate pinion several times to seat bearings.

Check bearing preload using an inch pound torque wrench applied to the pinion nut. The preload reading including drag of new seal should be 25-35 inch pounds with new bearings or 15 to 25 inch pounds for reused bearings. If preload torque is not within these specifications, reduce the total pinion spacer thickness .001″ for each 10 inch pounds preload desired, or decrease total pinion spacer thickness .001″ for each 10 inch pounds preload to be subtracted.

MASTER CYLINDER, REPLACE

1. Remove connector from stop light switch.
2. Disconnect brake pipe from master cylinder and tape end of pipe to prevent entrance of dirt.
3. Disconnect brake pedal from master cylinder push rod.
4. Unfasten master cylinder (4 nuts) from dash panel and remove cylinder.
5. Reverse removal procedure to install. Then bleed hydraulic system as outlined in the *Hydraulic Brakes Chapter.*

Front End & Steering Section

WHEEL ALIGNMENT

Caster & Camber

Caster and camber are adjusted by shimming at the upper control arm shaft attaching points. These shims are available in thicknesses of .030", .060" and .120".

Adding shims at the front locations will change caster toward negative with practically no change in camber. Adding shims at the rear locations will change caster toward positive and camber toward negative. Adding equal shims at both front and rear locations will not change caster but will change camber toward negative.

To adjust, loosen both front and rear bolts to free shims for removal or addition. After installing or removing shims (limit to .380" in any one stack) tighten and torque shaft bolts to 60-85 ft. lbs.

Toe-In, Adjust

Car must be at curb weight and running height; bounce front end and allow it to settle at running height. Steering gear and front wheel bearings must be properly adjusted with no looseness at tie rod ends. The car should be moved forward one complete revolution of the wheels before the toe-in check and adjustment is started and the car should never be moved backward while making the check and adjustment.

With front wheels in the straight ahead position, toe-in is adjusted by turning the tie rod adjusting sleeves as required. Left and right adjusting sleeves must be turned exactly the same amount but in opposite directions in order to maintain front wheels in straight ahead position when steering wheel is in straight ahead position.

The steering knuckle and steering arm "rock" or tilt as front wheel rises and falls. Therefore, it is vitally important to position the bottom face of the tie rod end parallel with the machined surface at the outer end of the steering arm when tie rod length is adjusted. Severe damage and possible failure can result unless this precaution is taken. The tie rod sleeve slamps must be straight down to 45° forward to provide clearance.

Fig. 1 Front suspension

WHEEL BEARINGS, ADJUST

1. Tighten spindle nut to 17 ft. lbs. torque and rotate hub to seat bearings.
2. Back off spindle nut ½ turn and retorque to one ft. lb.
3. Back off 1/12 turn minimum to ¼ turn maximum to allow installation of cotter pin.
4. Before installation of grease cap in hub, make sure end of spindle and inside of cap are free of grease so that radio static collector makes good contact. Make sure that static collector is properly shaped to provide good contact between end of spindle and grease cap.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure front wheel bearings are properly adjusted and that control arms are tight. Then check ball joints as follows:

To check lower ball joint, jack up under lower control arm (not under frame). Then grasp the tire at top and bottom and move it in and out. If the movement at edge of tire exceeds ¼", ball joint is worn and should be replaced.

To check upper ball joint, disconnect upper arm from steering knuckle. Then if stud and ball can be turned in the socket under finger rotation, or a shake or looseness is evident, the joint should be replaced.

FRONT END REPAIRS

Ball Joints, Replace

Upper and lower ball joints are similar in appearance but are not interchangeable. Upper ball joints are spring-loaded to prevent looseness while the force of the chassis spring keeps the lower ball loaded, Fig. 1.

If the upper stud has any perceptible shake, or if it can be twisted in its socket with the fingers, it should be replaced.

1. Support car on stand at body rail so front suspension is in full rebound

position.
2. Remove front wheel.
3. Remove ball stud cotter key.
4. Loosen, but do not remove ball stud nut.
5. Rap steering knuckle sharply in area of ball stud to allow force of chassis spring to disengage tapered stud from knuckle.
6. Place jack under lower control arm at spring seat. Raise jack until compression is relieved on upper control arm rubber rebound bumper.
7. Remove stud nut.
8. Use 1 9/16″ socket to thread ball joint out of control arm. Save rubber dust shield and grease fitting for reinstallation.
9. Lubricate new ball joint threads and install joint in control arm. Torque to 40 ft. lbs. *Excessive torque may strip threads in control arm.* Install grease fitting so it points toward centerline of car.
10. Turn stud so that cotter key hole is fore and aft and assemble rubber dust shield to stud.
11. Position tapered stud in knuckle and install nut. Tighten nut to a torque of 35-60 ft. lbs. and install cotter key. Install wheel.

Service Note

Care and good judgment must be exercised when installing ball stud in control arm. If ball stud is started incorrectly torque will be high although the stud is not threaded in until hex is against control arm. If 40 ft. lbs. torque on ball stud cannot be attained due to thread damage or other causes, the control arm must be replaced.

Shock Absorber, Replace

Unfasten shock absorber top and bottom and remove it through the spring seat. Check shock absorber for obvious physical damage or oil leakage. Push and pull shock absorber in an upright position. If smooth hydraulic resistance is not present in both directions, replace shock absorber.

Spring, Replace

1. Remove wheel with hub and drum.
2. Disconnect stabilizer link from lower control arm and remove shock absorber.
3. Disconnect lower control arm ball joint from steering knuckle.
4. Lower floor jack under spring until spring is fully extended and remove spring.

Fig. 2 Steering gear worm and ball nut

Fig. 3 Steering gear pitman shaft and ball nut

5. When installing spring, make sure end of spring with ground (flat) coil is at the top. Rotate spring so end of bottom coil will index with edge of hole in lower control arm spring seat. Complete the installation in the reverse order of removal.

Upper Control Arm

1. Disconnect upper ball joint from steering knuckle.
2. Remove control arm, carefully noting number, location and thickness of adjusting shims between shaft and frame bracket.
3. If shaft and bushings only are to be replaced, clamp control arm in vise and remove shaft and bushings.
4. Assemble new grease seals on shaft. Apply light coating of grease to shaft threads and position shaft in arm. Start new bushing in arm and thread shaft into bushing to aid in alignment. Tighten bushing into arm until hex section of bushing seats firmly into arm.
5. Start second bushing into threads of arm with shaft threaded into opposite bushing.
6. After bushing has been threaded part way into arm, rotate shaft to engage threads of second bushing as an aid in piloting bushing squarely into position.
7. Tighten bushing into arm until hex section of bushing seats firmly into arm. Shaft should be free enough to turn by hand. Install grease fittings and lubricate bushings.
8. Rotate shaft to make distance between shaft bolt holes and arm equal on both sides as nearly as possible.
9. Assemble upper control arm assembly, making certain the wheel alignment shims are correct. Torque shaft-to-bracket bolts to 60-85 ft. lbs.
10. Assemble ball joint.
11. Check and adjust wheel alignment if necessary.

Lower Control Arm

1. Remove coil spring.
2. Remove threaded bushings from control arm and remove arm from shaft.
3. Lightly coat shaft threads with grease and install rubber seals on shaft.
4. Position control arm on shaft and start front bushing onto shaft threads. Place a suitable spacer between control arm and crossmember to maintain control arm spread.
5. Thread front bushing into control arm. Tighten bushing until hex of bushing seats firmly into arm.
6. Remove spacer and install rear bushing as above.
7. Install coil spring.

HORN SOUNDER

1962

With Standard Wheel—Loosen one screw retaining the cap assembly. Disconnect horn contact wire from connector brush wire. Remove two screws retaining horn contact in cap.

To remove horn connector brush, remove cap and steering wheel. Remove staking from underside with a chisel and remove horn connector brush.

With Deluxe Wheel—Remove two retaining screws from actuator bar cap. Remove four clutch head retaining screws from actuator bar. Remove four plastic retaining rivets from contact plate.

To remove horn connector brush, remove actuator bar cap and bar. Lift ground plate and horn connector brush from steering wheel.

1961

The push bar contact on the standard steering wheel is retained in the cap by two screws. To remove either push button contact on the deluxe wheel, it is necessary first to remove the steering wheel. Then remove the wing-shaped shroud from wheel and contact from shroud.

If the horn connector brush is defective, it is necessary to remove the steering wheel. Then remove brush by using a chisel to unstake it from the wheel hub. Insert a new brush in wheel hub and stake in place.

Fig. 4 Steering shaft coupling

STEERING WHEEL

1962

1. Unplug horn ground wire connector at mast jacket to prevent horn from sounding.
2. On deluxe wheels, remove actuator cap, bar, springs and ground plate from wheel.
3. On standard wheels, remove cap assembly by inserting a screwdriver through hole in cap and loosening retaining screw. Unplug horn connector brush wire from cap.
4. Loosen wheel retaining nut several turns (do not remove).
5. Attach puller to wheel hub and pull wheel up to nut. Then remove puller, nut and wheel.
6. When installing wheel, note that location marks on wheel and shaft are provided to insure straight ahead position of wheel when front wheels are pointing straight ahead.

1961

1. To remove wheel, unplug ground wire connector at mast jacket to prevent horn from sounding.
2. Remove emblem from steering wheel. On standard wheel, remove cap by inserting a screwdriver through hole in cap and loosening retaining screw. Unplug horn connector brush wire from cap.
3. Loosen steering wheel nut several turns (do not remove). Attach suitable puller to wheel hub and pull wheel up to nut. Remove puller, nut and steering wheel.
4. When installing wheel, note that location mark on wheel and shaft are provided to insure straight ahead position for wheel when front wheels are pointing straight ahead.

MANUAL STEERING GEAR

The steering gear is the recirculating ball worm and nut type, Fig. 2. The teeth on the pitman shaft sector are slightly tapered so that a proper lash may be obtained by moving the pitman shaft endways by means of a lash adjuster screw which extends through the gear housing side cover, Fig. 3. The outer race or cup of the lower worm bearing is pressed into the worm bearing adjuster which screws into the housing and is locked by a nut, Fig. 2. The upper steering shaft is connected to the steering worm shaft through a universal joint type coupling, Fig. 4.

Steering Gear, Adjust

Never attempt to adjust the steering gear while it is connected to the intermediate rod. The steering gear must be free of all outside load to properly make any steering gear adjustments.

1. Torque steering gear-to-crossmember bolts to 55 ft. lbs.
2. Disconnect intermediate rod from pitman arm.
3. Turn steering wheel slowly from one extreme to the other. *Never turn wheel hard against end stops as damage to ball nut may result. If gear is hard pulling or binding it indicates an excessively tight adjustment of worm bearings or excessive misalignment of steering shaft. Roughness of gear indicates faulty internal parts. These conditions must be corrected before steering gear can be properly adjusted.*
4. Remove emblem or cap from steering wheel hub.
5. Turn steering wheel gently in one direction until it stops.
6. Attach an inch-pound torque wrench to steering wheel nut and check torque required to turn wheel steadily in the range where lash exists between ball nut and pitman shaft sector.
7. Torque required to keep wheel turning should be 2 to 7 inch pounds. If not within these limits, adjust worm bearing preload as follows:
8. Loosen worm bearing adjuster lock nut, Fig. 5. Turn bearing adjuster as required to bring wheel pull between 2 and 7 inch pounds. Tighten lock nut and recheck adjustment. Torque side cover bolts to 30 ft. lbs.
9. To check pitman shaft overcenter preload, turn steering wheel from one extreme to the other while counting the total turns; then turn wheel back ½ the number of turns. This positions gear on the high point where a preload should exist between ball nut and pitman shaft teeth.
10. A torque of 4 to 8 inch pounds *higher than the worm bearing preload* should be required to turn the wheel through the high point. Loosen the lock nut and turn the pitman shaft lash adjuster, Fig. 5, as required to obtain a total overcenter pull of not more than 13 inch pounds.
11. After tightening lock nut, rotate steering wheel back and forth through the high point and through the entire range to check for tight spots. *If lash cannot be removed at high point or if gear load varies greatly and feels rough, the gear should be removed for inspection of internal parts.*

Fig. 5 Steering gear adjusters

Steering Gear, Replace

1. *Due to lack of clearance it is necessary to remove gear from car to remove pitman arm and nut from pitman shaft.*
2. Remove lower coupling clamp bolt.
3. Loosen clamp that retains mast jacket to toe pan cover and U-bolt that retains jacket to instrument panel. Pull mast jacket up to expose lower coupling.
4. Remove lower coupling.
5. Disconnect pitman arm from intermediate rod.
6. Unfasten steering gear from front suspension crossmember (4 bolts) and remove gear from car. *Do not remove pitman arm from gear unless pitman shaft or seal are to be removed.*
7. Reverse removal procedure to install steering gear (see Fig. 6). Torque pitman arm nut to 95 ft. lbs. Torque steering gear attaching bolts to 55 ft. lbs.

Steering Gear Repairs

Using Fig. 7 as a guide, disassemble the steering gear, observing the following:

1. The lower worm bearing cup is not replaced separately but is serviced with the worm bearing adjuster.
2. If the side cover bushing is worn, the side cover must be replaced as the bushing is not furnished separately.
4. Inspect teeth of ball nut and pitman shaft for pitting or scoring which would require replacement of nut or pitman shaft.
5. Check pitman shaft surface for wear or scoring, then check fit of lash adjuster and shim in the slot in end of pitman shaft by inserting a feeler gauge between head of screw and bottom of slot. Adjuster must be free to turn and end play should not exceed .002". If end play exceeds .002", install proper shim. Shims are available in thicknesses of .063", .065", .067", and .069".
6. Lubricate all seals, bushings, bearings and gears with multi-purpose gear lube just before assembling.

Steering Gear, Assemble

1. Position ball nut over worm shaft so that deep side of teeth will be toward side cover when installed in gear housing.
2. Install 19 balls in each circuit. Rock worm shaft slightly to aid in installing balls.
3. Place 6 balls in each return guide, using grease to hold balls in place.
4. Install return guides, clamp and screws.
5. Rotate worm through its complete travel several times to insure balls are installed correctly and rotate freely.

Fig. 6 Correct worm to lower coupling attachment

6. Place upper bearing on worm shaft into housing.
7. Place lower bearing in worm bearing adjuster and install bearing retainer.
8. Install adjuster with lock nut in housing. Tighten adjuster only enough to hold worm bearings in place.
9. Turn worm shaft until center groove in ball nut lines up with center of pitman shaft bushing. Install pitman shaft and lash adjuster with shim so that center tooth meshes with center groove in ball nut.
10. Install side cover with new gasket on lash adjuster by turning adjuster counterclockwise. Install and torque side cover bolts to 30 ft. lbs.
11. Turn lash adjuster so that teeth on shaft and ball nut engage but do not bind. Install lash adjuster lock nut loosely.
12. To protect pitman shaft seal from damage, cover shaft splines with masking tape. Slide new seal into place and seat against shoulder in housing.
13. Install new worm shaft seal flush with surface of housing.
14. Fill gear with multi-purpose lubricant, install on car and adjust as previously described.

POWER STEERING

Service procedures on the power steering gear is given in the *Power Steering Chapter*. To remove the gear from the car, proceed as follows:

1. Disconnect hydraulic hoses from gear.
2. Remove two nuts that retain lower coupling to steering shaft flange.
3. Loosen clamp that retains mast jacket to toe pan cover and U-bolt that retains jacket to instrument panel.
4. Pull mast jacket up far enough to disengage steering shaft flange with flexible coupling.
5. Disconnect pitman arm from intermediate rod.
6. On cars with synchromesh transmission, remove lower coupling from gear stub shaft.
7. Remove steering gear from front suspension crossmember (4 bolts). *Do not remove pitman arm from housing unless pitman shaft or seals or rack piston nut are to be removed.*
8. Reverse removal procedure to install the gear. Tighten pitman arm nut to a torque of 95 ft. lbs. Torque gear attaching bolts to 55 ft. lbs.
9. On synchromesh cars, there must be at least $\frac{1}{16}''$ clearance between lower coupling and adjuster plug.
10. When installing the mast jacket, see that flange on steering shaft is properly positioned on flexible coupling. *Make sure coupling rivet heads are positioned in center of correct slots in flange. Small rivet goes in small slot and large rivet in large slot.*
11. After hoses are connected to steering gear, fill pump reservoir to correct level with automatic transmission oil. Start engine and maintain oil level in reservoir while allowing engine to idle at least three minutes before turning steering wheel. Then rotate steering wheel throughout its entire range slowly a few times to bleed system of air. Recheck oil level and for leaks.

Fig. 7 Exploded view of manual steering gear

Instruments, Radio & Windshield Wiper

INSTRUMENT CLUSTER

1. Remove cluster hood. Then from under instrument panel, remove two nuts from studs that retain cluster at each side.
2. Remove two screws that retain lower edge of cluster to instrument panel tie bar.
3. Disconnect wiring harness connectors from headlight switch, windshield wiper switch, ignition switch and cigar lighter.
4. Disconnect speedometer cable and printed circuit plug.
5. Remove cluster by pulling rearward and lifting up.
6. Remove speedometer and other instruments or switches from cluster as required.
7. When installing the cluster, *the projection on the disconnect plug must be lined up with the keyway in the printed circuit when assembling plug on connector pins.*

RADIO, REPLACE

1. On air conditioned cars it is necessary to lower the evaporator assembly by removing both right and left bolts that retain assembly to underside of instrument panel. Then remove the brace that supports radio, the screw that holds the two right sections of the air duct together and the glove box. Radio and speaker may then be removed through glove box opening.
2. Disconnect antenna lead-in wire, speaker wire and battery wire from radio.
3. Remove knobs, escutcheons and retaining nuts from radio control shafts.
4. Remove support bracket-to-radio cap screw located at right side of radio and lower radio from under instrument panel.
5. Installation is made in the reverse order of removal.

WINDSHIELD WIPER

The windshield wiper and washer switch is contained in the instrument cluster. To remove the switch it is necessary to remove the instrument cluster, the procedure for which is outlined above.

The wiper motor is held to the upper cowl by means of three bolts which fasten through three rubber bushings on the motor mounting plates and then into three weld nuts located in the cowl.

②—"A" mark for premium fuel, "C" mark for regular fuel.

③—Turn adjusting screw in (clockwise) until engine begins to misfire. Then turn screw ½ turn in opposite direction.

④—Adjust idle speed with air conditioner turned on.

⑤—The vacuum released parking brake must be made inoperative by pulling vacuum hose off right hand connector of the vacuum switch on the neutral safety switch and covering the switch opening with tape to prevent any air leak.

Engine Section

ENGINE MARKINGS

On models prior to 1961 an asterisk stamped on the cylinder block ahead of the engine unit number indicates a .010″ oversize cylinder bore. On 1961-62 models the asterisk follows the unit number.

The engine unit number is stamped on the bell housing portion of the crankcase behind the left hand cylinder block.

ENGINE, REPLACE

1. Drain cooling system.
2. Remove hood and radiator.
3. Disconnect fuel, oil and vacuum lines, and wires connected to engine units.
4. Remove generator, starter and carburetor.
5. Remove fan and pulley.
6. Disconnect power steering hoses.
7. On cars so equipped, disconnect refrigerant lines, exercising precautions outlined in *Air Conditioning* chapter.
8. Remove propeller shaft.
9. Remove Hydra-Matic linkage slush deflector.
10. Disconnect speedometer cable.
11. Disconnect shift linkage at transmission.
12. Disconnect front engine mounts.
13. Disconnect exhaust pipes at manifolds.
14. Unfasten and lower steering idler arm and connecting link.
15. Attach engine lifting rig.
16. Remove rear engine support bracket from frame and extension housing.
17. Lift out engine and transmission.
18. To install, reverse above operations.

Fig. 2 Cylinder head tightening sequence. All models

CYLINDER HEAD, REPLACE

Drain radiator and cylinder block on side on which head is to be removed. If left head is to be removed, take off power steering pump, generator and disconnect water temperature wire. If right head is to be removed, disconnect windshield wiper pipe clamp, and the compressor on air conditioned cars. If both heads are to be taken off, proceed as follows:

1. Remove oil filter lines as necessary.
2. Remove two capscrews from water pump flange at cylinder head and loosen remaining capscrews about three turns.
3. Remove carburetor air cleaner.
4. Remove carburetor-to-fuel filter line.
5. Remove ground strap screws from rear of head at cowl.
6. Remove vacuum advance line from carburetor.
7. Disconnect intake manifold vacuum pipe hose.
8. Disconnect coil wires at distributor.
9. Disconnect carburetor linkage.
10. Remove choke heater pipe.
11. Remove rocker arm covers and distributor cap.
12. Remove intake manifold.
13. Remove exhaust pipe and heat valves.
14. Remove rocker arm assembly.
15. Remove push rods.
16. Remove cylinder heads, using lifting hooks in the first and third spark plug holes.
17. Reverse removal procedure to install the heads, tightening the capscrews in the sequence shown in Fig. 2.

VALVE ARRANGEMENT

Front to Rear

All Models ..... E-I-I-E-E-I-I-E

ROCKER ARMS

Sludge and gum formation in the rocker arms and shafts, Fig. 3, will restrict the normal flow of oil to the rocker arms and valves. Therefore, each time the assemblies are removed, they should be disassembled and thoroughly cleaned.

Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When the assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves.

Check each push rod for a bent condition. If bent more than .020″ when checked with a dial indicator, replace the push rod. Do not attempt to straighten a bent push rod. If a dial gauge is not available, at least check the rod for straightness by

Engine lubrication. 1960-62

Engine lubrication. 1955-59

rolling it on a perfectly flat surface plate. *Push rods should be installed with the double grooved end up on 1952-54 engines and with single grooved end up on 1955-56 and early 1957.*

Service Note

An incorrectly installed rocker arm shaft permits oil to be sprayed directly on the valve stems. This causes an excessive amount of oil to be drawn past the guides into the combustion chamber, increasing oil consumption. When the rocker arm shaft is correctly installed, the notch on the end of the shaft faces down and toward the center of the engine, Fig. 3.

VALVES, REMOVE

With cylinder head removed as outlined previously, use a suitable valve spring compressor to compress the springs in order to take out the valve locks, Fig. 4. Then remove spring retainers, valve stem seals and valve springs. Remove burrs from valve stem lock grooves to prevent damage to valve guides, and slide valves from heads.

Place valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to the original guide holes.

VALVE GUIDES

Check valve stem to guide clearance, using a $\frac{1}{16}''$ wide strip of .005″ brass shim stock on a "no-go" basis. Bend the end of the shim and hang it in the end of the valve guide. Shim should not extend more than ¼″ into the guide. If valve stem will enter guide, clearance is excessive and valve and guide should be replaced to prevent excessive oil consumption and improper seating of valves.

Unless the special tool shown in Fig. 5 is available, before removing a guide, measure the distance it sticks out of the valve port with a steel scale. Then drive out the old guide and install the new one to the measured depth.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 5A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 3 Rocker arm details

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}''$ to $\frac{5}{64}''$, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

Fig. 4 Tool used for removing and installing valves

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, Fig. 6, if one is available, and according to the specifications given in the *Valve Specifications* table.

If a spring tester is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVES, GRIND

New valve heads have a seat angle of 44 degrees to provide a hairline contact between the head of the valve and the valve seat in the cylinder head which assures good seating of the valve and less chance of burning the valve head due to exhaust gas leakage. *Servicemen may, however, reface valves at a 45 degree angle.*

Valve seats should be cut so there is $\frac{1}{32}''$ from the outer edge of the seat to the edge of the flange on the valve head to allow heat to escape and to provide maximum life for newly ground valves.

Cars operated at moderate or slow speeds in city driving should have a valve seat width of $\frac{3}{64}''$ to $\frac{1}{16}''$. For cars driven

Fig. 5 Valve guides are correctly installed with tool shown

a great deal at high speeds the seat width should be $\frac{1}{16}''$ to $\frac{3}{32}''$ to assure adequate cooling.

Test valves for concentricity with seats and for tight seating. Valves can be tested. by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. Both tests are necessary to prove that a proper seat is being obtained.

HYDRAULIC VALVE LIFTERS

Fig. 7

Failure of a hydraulic valve lifter is generally caused by an inadequate oil supply or dirt. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

Removing 1958-62 Lifters

The push rod holes in the engine block are large enough to permit the removal of the hydraulic lifters without removing the intake manifold. Therefore, when replacing hydraulic lifters in relatively new engines, or in those engines that have a minimum build-up of gum and varnish on the lifter body, do not remove the intake manifold. Instead, proceed as follows:

1. Remove rocker arm cover.
2. Remove rocker arms. If rocker arm assemblies are to be disassembled, it is extremely important upon assembly that the large side of the rocker support bosses face the exhaust valve.
3. Remove push rods, keeping rods in order as they are removed.
4. With the aid of mechanical fingers or a magnet attached to a long rod, remove the lifters through the push rod openings.

Note: If, because of gum and varnish the lifters cannot be removed as outlined above, it will be necessary to follow the procedure outlined for earlier models.

Removing 1955-57 Lifters

1. Remove right and left rocker arm covers along with coil, high tension wiring, and bracket from cylinder heads and hang on cowl.
2. Remove intake manifold.
3. Remove three valve compartment cover screws.
4. Loosen engine ventilator pipe clamp screw at flywheel housing, move pipe out of the way, and remove valve compartment cover.
5. Remove right and left rocker arm assemblies. When only one or two valve lifters are to be removed, it is not necessary to remove the complete rocker arm assembly. Merely compress the valve spring, slide the rocker arm over and remove the push rod.
6. Remove push rods.
7. Using the tool shown in Fig. 8, remove lifters from engine, being sure to keep them in order so that they can be reinstalled in the same bore from which they were removed. Rotate valve lifter back and forth while lifting them out to remove any carbon or varnish from base of lifter.

Servicing Lifters

To disassemble, press down on the center of the push rod cup. Using a pointed tool, remove lock wire from the groove while holding cup down. Invert lifter and slide out push rod cup, plunger, ball retainer and spring.

To assemble, place the ball on its seat in the lower end of the plunger while holding the plunger upside down. Position the ball retainer and spring over ball and end of plunger. Lower the body over the plunger. Turn the assembly right side up and fill the plunger with clean engine oil. Jiggle the ball with a small piece of wire until oil drains out of plunger into the body and trapped air is released from the body. Refill the plunger with oil, place the push rod cup on the plunger and position the lock wire over the cup, locking it in its groove.

TIMING CHAIN & COVER

To remove the timing chain and sprockets, proceed as follows:

1. Turn engine over until distributor rotor is under the number six contact in the distributor cap.
2. Remove water pump and oil pan.
3. Remove crankshaft pulley.
4. Take off chain cover.
5. Remove two capscrews attaching sprocket to camshaft. Then remove chain together with camshaft sprocket.
6. Pull crankshaft sprocket.
7. To install the sprockets and chain, reverse the foregoing procedure, being sure to have the sprocket marks lined up as shown in Fig. 9 when the chain is installed.

Fig. 5A Checking valve spring installed height

Fig. 6 Valve spring tester

Fig. 7 Hydraulic valve lifter. All models

Fig. 8 Special pliers used to remove stuck valve lifters

Fig. 9 Showing timing marks lined up for correct valve timing

CAMSHAFT & BEARINGS

1. To remove the camshaft, remove hood lock plate support.
2. Remove Air Conditioning condenser (if equipped).
3. Remove radiator core and water pump.
4. Remove timing chain and sprockets.
5. Remove distributor.
6. Remove valve lifters.
7. Slide camshaft forward carefully until it is out of engine. Use care to avoid allowing cam lobes to scratch camshaft bushings.
8. Installation is made in the reverse order of removal.

PISTONS & RODS, REMOVE

After removing the cylinder head, examine the cylinder bores above the ring travel area. If bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove connecting rod caps and push the pistons and rods out of cylinders, using care to prevent rod bolts from contacting and nicking crankshaft journals.

Make sure that rods and pistons are properly numbered so that they can be reinstalled in original locations. It is advisable to install the caps on the rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

On all engines, assemble and install the piston and rod assemblies as shown in Fig. 10.

PISTONS

Service replacement pistons are furnished by Cadillac in standard sizes and .010, .020 and .030 in. oversizes, with rings and pins fitted.

Before ordering pistons for replacement, it is extremely important to determine the size of the cylinder bores by actual measurement. Actual measurement at the time of replacement is the only certain way to avoid errors.

Where no micrometer or dial gauge is available to measure piston clearance, the use of a feeler gauge will serve satisfactorily as there is a definite relation between feeler gauge pull in pounds and micrometer clearance in thousandths of inches, as shown in Fig. 11, which is set up for .002, .0025 and .003 in. feeler gauge thickness.

In order to obtain the piston clearance at the upper end of the skirt, it is necessary to insert the piston into its upper extreme position, along with the feeler ribbon, which must be kept located over the vertical slot and not in excess of ½ in. below the upper end of the skirt. It is advisable to mark the feeler ribbon adjacent to the piston head so that its proper location on the piston can be maintained. When the proper clearance is established, it should require the amount of pounds pull on the scale shown in Fig. 11 to withdraw the feeler, depending upon the thickness of the feeler ribbon being used.

Fig. 10 Connecting rods and pistons

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin (thrust side of piston). Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is important that refinished cylinder bores are trued up to have not over .0007 in. out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must washed to remove all traces of abrasive and then dried thoroughly. The dry bore should be brushed clean with a power-driven fiber brush. If all traces of abrasive are not removed, rapid wear of new pistons and rings will result.

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the piston is checked for fit in the cylinder bore; therefore the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees F. between parts is sufficient to produce a variation of .0005 in.

PISTON RINGS

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bores' diameter. This is done with a "Glazebuster"

or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and ring clearances will be excessive.. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

See the *Piston and Ring Data* chart for end gap clearances.

To check the end gaps of piston rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the ring carefully with a smooth file.

PISTON PINS

Piston pins are a matched fit with the piston and are not available separately. Piston pins are pressed in the connecting rods and will not become loose enough to cause a knock or tapping until after very high mileages. In such cases a new piston and pin assembly should be installed.

ROD BEARINGS

Connecting rod bearings are of the precision insert type, and if worn beyond .0045 in. can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves. The clearance between the connecting rod bearing and the crankshaft can be measured by the use of Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall cap and tighten to the torque value given in the *Engine Tightening Data* table.
4. Remove bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage envelope. The number within the graduation on the envelope indicates the clearance in thousandths of an inch, Fig. 12. If this clearance is greater than .0045 in., replace the bearing.

Fig. 12 Checking bearing clearance with Plastigage

Fig. 11 Piston clearance chart

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening Data* table.

CRANKSHAFT OIL SEAL

Braided Type, 1955-58

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade, Fig. 13.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

Lip Type Seal, 1958-62

After 1958 Engine No. 050909 a new lip type rear main bearing seal entered production. Due to differences in the groove in the main bearing cap and cylinder block, this new seal is *not* interchangeable with the earlier braided type. Replacement of the new lip type seal may be accomplished without removing the crankshaft, using the following procedure. The two seal halves are identical and can be used in either the upper or lower location.

1. Be sure grooves in bearing cap and block are clean, dry and free from burrs.
2. Start upper half of seal in block and rotate seal into position. Then press firmly on both ends of seal to be

Fig. 13 Installing braided type rear main bearing oil seal. 1955-58

sure that it is protruding uniformly on each side.

3. Install lower half of seal into bearing cap with lip facing forward and with one end of seal over ridge and flush with split line. Hold one finger over this end to prevent it from slipping and push the seal into seated position by applying pressure to other end. Be sure seal is pressed down firmly and that it protrudes uniformly on each side. *Avoid pressing seal into position by applying pressure to the lip as damage to the sealing edge could result.*
4. Prior to assembly of main bearing cap on block, apply rubber cement to cap and block to act as a sealer, *being sure to keep the rubber cement off the seal lip and bearing surface to avoid damage to seal and engine.*
5. Lubricate lip of seal with thin film of engine oil.
6. Install bearing cap with screws finger tight. Then, using plastic hammer, drive crankshaft forward, then rearward, then forward again to assure proper alignment of bearing thrust faces.
7. Tighten bearing cap bolts to recommended torque. Then turn crankshaft at least one revolution to make sure it is not binding.

OIL PAN, REPLACE

1. Disconnect battery ground strap.
2. Remove oil level indicator.
3. Disconnect wires from starter solenoid and remove starter motor.
4. Unfasten idler arm support from frame.
5. On 1956-58 models, remove water hose and clip from center of crossmember. On 1959-60 models, remove right exhaust pipe bracket. On 1961-62 loosen exhaust manifold and remove heat control valve, and swing exhaust pipe out of the way.
6. Unfasten and remove pan.
7. To install, place new cork seals in rear main bearing cap and front cover, being sure ends of gaskets are in recess provided for them.
8. Cement pan gaskets to both sides of pan, lining up holes in gaskets with those in pan.
9. Place a small amount of chassis grease on each of the four corners of the pan gasket which hang over the front and rear cut-outs, which will permit the pan gasket to slide over corks and insure a good seal.
10. Place pan in position over four studs and install nuts and washers loosely.
11. Install remaining screws.
12. Install idler arm support, starter motor, and oil level indicator.
13. Replace oil and connect battery.

OIL PUMP REPAIRS

1959-62

To remove the pump, drain engine oil and remove oil pan. Unfasten pump from engine and disassemble as follows:

1. Remove oil pump float.
2. Remove oil pressure regulator valve and spring from pump body.
3. Remove pump bottom cover.
4. Slide idler gear out of pump body.
5. Remove pin from collar on end of drive shaft and press collar off of shaft.
6. Slide oil pump drive gear out of pump body.

Inspect strainer screen for dirt and float for leaks. Look for nicks or burrs or nicks on pressure regulator valve which might cause leaks or binding in pump body. Inspect pump gears for nicks and burrs. Inspect bottom cover for wear and dress down on a surface plate if necessary. Place bottom cover on pump and check drive shaft end play. If end play exceeds .006 in., replace drive and idler gears. Assemble and install oil pump in the reverse order of its removal and disassembly.

OIL & VACUUM PUMP REPAIRS

1955-58

The oil pump on these models is the same as past models except for the addition of a vacuum pump which is mounted on the bottom of the oil pump for windshield wiper operation. The Vacuum pump is the vane type and is driven by the oil pump through a hexagonal shaped drive key.

Vacuum Pump Test

Disconnect the vacuum pump hose leading from the crankcase at the check valve on the cowl. Connect a vacuum gauge to the vacuum pump hose and start the engine. If the vacuum pump is operating properly, the gauge will show a minimum of 20" mercury at sea level at 3600 rpm engine speed. If the gauge does not show this reading the pump is defective or there is a leak in the vacuum lines. If the vacuum does not increase after tightening the vacuum connections, replace the vacuum pump.

Vacuum Pump, Replace

Remove oil pan and baffle. Disconnect vacuum line at engine block. Unfasten the vacuum pump from the oil pump and remove the vacuum pump with the oil pump idler gear. Remove hexagonal drive shaft, and the vacuum line from the pump.

Installation is made in the reverse order.

RADIATOR, REPLACE

Service Note

When it is necessary to remove both the radiator and water pump to perform other work on the engine, time will be saved if these parts are removed as a unit rather than as separate units, because of the difficulty of removing the upper and lower radiator hoses.

Drain cooling system and disconnect heater hose at water pump. Remove generator drive belt and all radiator and water pump attaching screws. Then lift the radiator and pump as an assembly.

On cars so equipped, it will also be necessary to remove the oil filter and/or power steering pumps from their brackets.

1955-57

To remove the radiator, drain cooling system and loosen upper and lower radiator hoses. On 1955-57 Air Conditioned equipped cars, remove condenser assembly. Remove six screws (also four spacers on Air Conditioned cars) which hold radiator to support. Lift out radiator with hoses.

When installed, the space between the radiator and the front edge of the fan blade assembly should be ½ to 1" for efficient fan operation.

1958-62 Standard Cars

1. Drain cooling system and disconnect hoses from radiator.
2. Disconnect two transmission cooler lines from radiator lower tank. Plug ends of lines to prevent loss of transmission fluid.
3. Unfasten and remove radiator from its cradle.

1958-60 Air Conditioned Cars

1. Drain cooling system and disconnect hoses from radiator.
2. Remove Freon hose retainer clip from right hand upper side of radiator cradle.
3. Unfasten condenser and dehydrator receiver from bracket on right and left sides of radiator. Access to lower screw on right side of radiator may be gained through grille.
4. Remove left tie bar between radiator cradle and hood lock plate.
5. On 1958, lift out condenser and dehydrator receiver assembly and swing to one side. Do not disconnect Freon lines, as flexible lines allow the condenser, with attachments, to be swung out over fender or out of the way. Remove six screws attaching radiator assembly and condenser brackets to radiator cradle and remove brackets.
6. On 1959 tilt condenser and dehydra-

tor-receiver assembly forward, but do not disconnect Freon lines, as flexible line will allow the condenser, with attachments, to be moved out of the way.
7. Pull radiator forward until inlet and outlet necks clear radiator hoses and lift radiator up and out.
8. Reverse removal procedure to install the radiator. Then run engine long enough to pump coolant through entire system and check radiator and transmission fluid levels. On standard cars, it is important for efficient fan operation that radiator to fan clearance be ½" to 1".

1961-62 Air Conditioned Cars

1. Drain cooling system and disconnect radiator hose.
2. Disconnect two transmission cooler lines from the radiator lower tank, and plug ends of lines to prevent loss of transmission fluid.
3. Remove two top and two bottom cradle-to-shroud clamps, and push shroud away from radiator.
4. Remove radiator by lifting straight up.
5. Reverse removal procedure to install.

WATER PUMP, REPLACE

1961-62 Standard Cars

1. Drain cooling system and remove air cleaner.
2. Disconnect radiator and heater hoses.
3. Remove power steering and generator drive belts.
4. Disconnect throttle return spring and remove power steering pump bracket screws. Then move pump to one side without disconnecting hoses.
5. Remove attaching screws and pump from engine.
6. Reverse removal procedure to install pump.

1961 Air Conditioned Cars

1. Drain cooling system and remove air cleaner.
2. Disconnect radiator and heater hoses.
3. Remove Freon compressor, power steering pump and generator belts.
4. Remove fan and pulley. Also throttle return spring on 1962.
5. Remove fan shroud. (1961).
6. Remove the two water pump-to-cylinder block screws that also retain the Freon compressor front mounting bracket to right upper and lower water pump flanges.
7. Remove Freon compressor front mounting bracket-to-cylinder head screw.
8. Remove remaining screws and lift off water pump.
9. Reverse removal procedure to install parts removed.

1958-60 Standard Cars

1. Drain cooling system.
2. Remove generator and power steering drive belts.
3. Disconnect throttle return spring, upper and lower hoses from radiator, and heater hoses from water pump.
4. Remove power steering pump and bracket and swing to one side (do not disconnect hoses).
5. Remove oil filter, disconnecting oil lines at filter.
6. Unfasten and remove water pump.

1958-60 Air Conditioned Cars

1. Drain cooling system.
2. Remove fan shroud (upper half on 1958).
3. Remove drive belts for Freon compressor, power steering pump and generator.
4. Disconnect upper and lower radiator hoses and heater hoses from water pump.
5. Remove power steering pump and bracket and swing to one side (do not disconnect hoses).
6. Disconnect throttle return spring and oil filter unit, disconnecting oil lines at filter.
7. Remove two water pump-to-cylinder block screws that also retain the Freon compressor front mounting bracket.
8. Remove Freon compressor front mounting bracket-to-cylinder block screw. Also on 1958, remove generator adjusting link-to-Freon compressor mounting bracket screw.
9. On 1958, loosen front Freon compressor adjusting link-to-mounting bracket screw, and swing lower portion of front mounting bracket toward right side of car.
10. Unfasten and remove fan and pulley.
11. Unfasten and remove water pump.

1958-60 Air Suspension Cars

Procedures for removing the water pump as outlined above may be followed as required. However, in order to move the power steering pump and air compressor out of the way, it will be necessary to disconnect the air lines from the air compressor.

1955-57

1. To remove the pump, drain cooling system.
2. Remove power steering pump drive belt (if equipped).
3. Remove drive belts.
4. Remove upper and lower radiator hoses and heater hoses from water pump.
5. Remove power steering pump and bracket and place to one side (if equipped).
6. Unfasten and remove pump from engine.
7. On Air Conditioned cars, remove two screws which secure compressor mounting bracket to right upper and lower water pump flanges. Loosen compressor support-to-cylinder block screw and move support away from water pump. Then unfasten and remove water pump from engine.
8. Reverse the foregoing procedure to install the pump.

WATER PUMP REPAIRS

When disassembling the pump, note that the thermostat is installed with the element downward and that the jiggle valve on the thermostat hangs open, thus making it easier to fill the radiator.

To disassemble, remove the thermostat housing and lift the thermostat from the pump body. Remove the pulley, and take the bearing retainer ring from the pump body. Be careful not to compress the retainer too far as this will weaken it and possibly allow the ring to come out.

Take off the cover plate. Press the shaft, bearing, hub and slinger out of the impeller and pump body toward the fan pulley end. Remove the impeller from the body, and take out the wear washer, spring and seal from the body.

It should be noted that the wear washer contacts the pump body. It is extremely important that the face in the pump body that contacts this wear washer be free from nicks, burrs or ridges. A tool for refinishing this seat is available and must be used every time a new seal is installed.

Note, also, that a permanently sealed bearing is used at the front end of the pump body and is retained by a wire retaining ring. The bellows type seal that slides over the water pump shaft holds the wear washer against the pump body. This is held in position when the impeller is pressed on the rear end of the pump shaft.

To assemble the pump, press the shaft bearing hub and slinger assembly into the body, making sure it is pressed against the end of the bearing bore in the body. Assemble the wear washer and seal over the driving lugs of the slinger from the rear side of the pump. It is important that the wear washer slides freely on the driving lug of the slinger, as any bind here will cause a leak.

Press the impeller on the shaft until the back of the impeller is .005 to .010" inside the cover face of the body but still does not touch the inner face. Be sure to support the opposite end of the shaft when pressing on the impeller to prevent damage to the housing and bearing.

DISTRIBUTOR, REPLACE

1. To remove the distributor, disconnect primary wire from coil.
2. Disconnect vacuum line from vacuum advance unit on distributor.
3. Crank engine until top dead center for No. 1 cylinder ("C" mark on vibration damper) is reached.
4. On 1956 remove distributor cap.
5. Remove distributor hold down nut and clamp.
6. Lift distributor from engine.

Service Note

The distributor rotor will turn slightly as the drive gear becomes disengaged from the teeth on the camshaft gear.

On cars prior to 1956, scribe a line on the edge of distributor cap, directly below the tip of the rotor. This will insure proper engagement of the drive gear teeth with the camshaft teeth to retain correct timing when reinstalling the distributor.

To retain correct timing on 1956, it is

Fig. 14 Ignition details. 1955

Fig. 15 Ignition details. 1956-62

advisable to crank the engine until the copper contact on top of the rotor points directly to the rear of the engine before removing the distributor.

When the 1956 distributor is installed, fill the oiler tube with 10-W oil.

IGNITION TIMING

To set the timing, refer to Figs. 14 and 15 and proceed as follows:

1. Adjust distributor clamp nut to allow the distributor to be turned without excessive looseness.
2. Disconnect vacuum advance pipe to carburetor and place a piece of tape over end of pipe. *This is important as carburetor trouble can affect timing adjustments.*
3. Insert a rod or pin alongside No. 1 wire in distributor cap.
4. Connect a suitable timing light to the rod or pin.
5. Make certain that the timing marks and timing pointer are clean.
6. Start the engine and warm up to operating temperature, making sure the carburetor is on slow idle before proceeding.
7. Observe the timing light flashes on the timing marks in relation to the pointer. Rotate the distributor so that the light flashes as the pointer and chalk line are opposite each other. *In localities where gasoline of the required octane rating is not available, the ignition timing may be retarded toward the "C" line on the vibration damper to eliminate spark knock.*
8. Insert the rod or pin alongside No. 6 wire and note the chalk line with relation to the pointer when the light flashes. If the light flashes before or after the chalk line, set the distributor to divide the variance. If this variance is excessive, the distributor and its alignment should be checked.
9. Tighten the clamp nut to 15-18 lbs. ft. torque and recheck the timing to make sure it did not change.
10. Remove the tape from the carburetor pipe and connect the pipe. *Then if the timing advances with the engine idling, it is a fair indication that the throttle valves are open and the carburetor needs adjustment or repairs.*

STARTER, REPLACE

Remove battery cable at starter solenoid and starter button wire at solenoid terminals. Remove the two mounting bolts at flywheel housing and pull starter forward.

Carburetor Section

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor

icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves, and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

CARTER CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

Year	Carburetor Model	Idle Adjustments★			Float Level		Float Drop		Pump Travel Setting	Choke Unloader Setting	Choke Setting

CARTER NOTES

IDLE SPEED SETTING

1955-62—In making the idle adjustment on the engine, an air adjustment screw is used in a similar manner as the conventional throttle speed screw used on earlier models. The idle air screw is located in the throttle body and can be identified by it being larger than the idle mixture screws. Turning the air screw outward increases engine speeds but also leans the mixture. This must be compensated for by adjusting the idle mixture screws.

1960-62 With Cruise Control—Idle adjustment procedures are the same as outlined for earlier models. However, because of the vacuum-released parking brake, it is impossible to set the brake with the transmission selector in "Dr" position unless the vacuum release is disconnected. Therefore when adjusting idle speed (with selector lever in "Dr") it is necessary to disconnect temporarily the vacuum diaphragm at the neutral safety switch and tape the switch opening to prevent any air leak which would affect the idle adjustment.

AIR CONDITIONER FAST IDLE DEVICE

This adjustment must be made after the carburetor is installed, engine at normal operating temperature and slow idle adjustment is completed.

1955-62 (except 1958)—With shift lever in neutral and air conditioner turned on, engine should idle at 900 rpm (800 on 1953-54). To adjust, loosen lock nut on diaphragm shaft and adjust knurled nut as required.

1958—Place shift lever in drive range. Disconnect short wire from terminal at front of refrigeration compressor to stop compressor. Turn air conditioner on and turn temperature control switch toward cooler position. Loosen fast idle device lock nut on diaphragm shaft and turn knurled nut to idle engine at 525 rpm. Tighten lock nut and connect wire to compressor.

METERING ROD

WCFB—This adjustment must be made after the pump setting. Seat throttle valves in bores of carburetor and loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—AFB float level. Adjust by bending float lever.

Fig. ②—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ③—Measure from top of float bowl cover to top of plunger shaft with throttle connector rod in inner hole of pump arm. Adjust by bending throttle connector rod.

④—Same as ⑧ except pump connector link is placed in outer hole of pump arm.

CARTER NOTES
continued

Fig. ⑥—WCFB float level. Adjust by bending float arms.

Fig. ⑦—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑤—With throttle valve wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader lip on throttle shaft lever.

Fig. ⑧—With pump connector link in inner hole of pump arm, flat on pump arm should be parallel with a straightedge placed on dust cover boss. Adjust by bending throttle connector rod.

⑨—With engine running at hot idle speed, open throttle wide momentarily and allow plunger to come out. Let throttle snap shut. If engine races plunger is too long; if engine stalls plunger is too short. Adjust for best results.

⑩—With engine running at normal operating temperature, turn fast idle screw against high step of fast idle cam or at index mark until specified rpm is obtained.

ROCHESTER NOTES

①—Turn fast idle screw against highest step on fast idle cam until the specified rpm is obtained.

②—With engine running at hot idle speed, open throttle wide momentarily and allow plunger to come out. Let throttle snap shut. If engine races plunger is too long; if engine stalls plunger is too short. Adjust for best results.

ROCHESTER NOTES continued

Fig. ⑥—4GC float drop.

Fig. ⑦—With throttle valves closed, measure from top of air horn casting to bottom of pump plunger shaft. Adjust by bending pump rod.

⑧—Bend unloader tang on fast idle cam to obtain specified clearance between edge of choke valve and dividing air horn wall with throttle valves wide open.

Fig. ⑨—Make fast idle setting first. Then with fast idle screw placed on highest step of fast idle cam, vent valve should just be closed. To adjust, bend tang on pump lever.

Fig. ⑫—4GC float drop.

Fig. ⑩—4GC float level.

Fig. ⑪—4GC float level.

ROCHESTER NOTES
continued

Fig. ⑬—4GC float drop.

Fig. ⑭—Make pump rod adjustment before adjusting idle vent valve as shown.

Fig. ⑮—With primary throttle valves closed against a wire gauge of the size listed, bend idle vent tang so that tang just touches face of valve.

Hydra-Matic Transmission Section

HYDRA-MATIC DRIVE

Manual Linkage, 1955

Fig. 1. Disconnect manual control rod from control lever at transmission. Move the control lever at the transmission to its normal drive position. The drive position can be found by moving the manual lever at the transmission fully forward and upward and then moving it rearward until the first detent is felt. Move the lever to the "DR-4" (left hand arrow) position.

Adjust the clevis pin the lower end of the control rod until the clevis pin can be inserted freely through the clevis and manual control lever. Assemble clevis, pin and lever and install cotter pin.

Manual Linkage, 1956-60

1. Loosen adjusting nuts on transmission manual rod and back off about 1", Fig. 2.
2. Place manual lever on transmission fully forward to Park position.
3. Place selector lever on steering column in Park position.
4. Slide clevis on manual lever along manual rod in the direction of steering column until all slack in linkage is taken up. *If clevis contacts upper adjusting nut before all slack is taken up, the nut should be backed of still further.*
5. Tighten lower adjusting nut with fingers against clevis to further remove slack. Bring upper adjusting nut down to contact clevis and tighten with wrench.
6. Check manual selector lever in car. It should be free to enter the Park position, and the Dr-4 stop in the steering column should correspond to the Dr-4 detent position in the transmission. Readjust if these conditions are not met.
7. Check to see that the indicator pointer indexes to the Dr-4 position when selector lever is at Dr-4 stop. Adjust if necessary.

Manual Linkage, 1961-62

1. Remove slush deflector.
2. Remove clevis from manual lever on transmission.
3. Loosen adjusting nuts on transmission manual rod.
4. Place manual lever on transmission in DR-4 position.
5. Place selector lever on steering column in DR-4 position.
6. Adjust length of manual rod until hole in manual lever lines up with hole in clevis and then *increase length one more turn.*
7. Install clevis and tighten adjusting nuts.
8. Check manual selector lever; it should be free to enter "Park" position, and DR-4 stop in steering column should correspond to DR-4 detent position in transmission. Readjust if these conditions are not met.

Throttle Linkage, 1955

1. Using Fig. 1 as a guide, remove throttle control clevis pin and check lever position with Tool No. J-3065-C by fitting tool to rear face of transmission case and inserting clevis pin through lever and "49 E 50" hole in tool while lever is in rearward position. If throttle lever is misaligned, correct by bending with Tool J-3310.
2. Assemble linkage to transmission throttle lever and install cotter pin.
3. Remove spring clip from carburetor-to-dash relay rod trunnion from relay lever.
4. Place ¼" drill shank through gauging hole in dash relay lever and into dash relay bracket.
5. With engine running, set throttle lever in hot idle position (Air Conditioner off).
6. Adjust carburetor-to-dash relay rod trunnion to allow free entry into dash relay lever.
7. Install spring clip in trunnion.
8. On cars with one carburetor, back off both jam nuts on the T.V. rod at carburetor to allow freedom of movement of rod in trunnion. Push end of T.V. rod to position transmission throttle valve against its stop. Bring rear jam nut up against trunnion and back off 8 flats (1⅓ turn). (This adjustment may be increased or decreased to improve shift characteristics after road test.) Tighten front jam nut, and check to make certain linkage moves freely.
9. On cars with two carburetors, remove lock nut, adjusting nut and spring from forward end of T.V. rod. Back off rear lock nut and adjusting nut on T.V. rod to permit free movement of rod in trunnion. Push on end of T.V. rod to position transmission throttle valve against its stop. Bring rear adjusting nut up against trunnion and back off 3 complete turns. Tighten rear lock nut. Install spring and adjusting nut on front end of T.V. rod. Adjust nut until distance between front face of trunnion and rear face of adjusting nut is 1 13/32". Install lock nut against front end of adjusting nut.
10. Continue on all cars by removing ¼" drill. Accelerator pedal should touch floor mat with slight pressure (allow ½" clearance if mat has been removed), when throttle is wide open.
11. Adjust accelerator pedal position at pedal end of dash relay-to-accelerator pedal rod.
12. Road test car to insure proper shifting characteristics.

Throttle Linkage, 1956-62

1. Remove spring clip from carburetor throttle rod trunnion and remove trunnion from relay bracket lever.
2. Place ¼" drill shank through gauging hole in dash relay lever and into dash relay bracket, Fig. 2.
3. With engine running, set throttle lever in hot idle position (Air Conditioner off).
4. Adjust carburetor throttle rod trunnion to allow free entry into dash

Fig. 1 1955 Hydra-Matic throttle linkage

Fig. 2 Manual and throttle control linkage. 1956-62

relay lever.
5. Install spring clip in trunnion.
6. Using two wrenches, back off both jam nuts on T.V. rod at carburetor to allow free movement of rod in trunnion, Fig. 3.
7. Push end of T.V. rod toward rear of car to position transmission throttle lever against its stop.
8. Turn front jam nut against the trunnion until all slack is taken up. Tighten nut 3 full turns for both one and two-carburetor engines.
9. Turn rear jam nut into contact with trunnion and use two wrenches to tighten nuts, being careful not to put any binding force on the carburetor plate.

HYDRA-MATIC TRANS., REPLACE

1955

1. Remove propeller shaft.
2. Disconnect battery and remove starter.
3. On 1955 models, remove flywheel housing front cover.
4. If equipped with oil cooler, disconnect hoses and plug hose ends to prevent loss of coolant.
5. Remove slush deflector.
6. On models prior to 1955, remove flywheel housing lower cover.
7. Drain transmission at oil pan and torus cover.
8. Support rear of engine with a jack.
9. Remove filler tube from transmission oil pan.
10. With a separate jack, raise transmission just enough to take strain off rear engine support.
11. Disconnect rear engine support from extension housing. Remove cross member that carries support.
12. Remove control rods from side of transmission.
13. Disconnect speedometer cable.
14. Unfasten and remove torus cover from flywheel.
15. Lower jack under engine to gain access to the upper flywheel housing-to-engine bolts, and remove bolts.
16. Remove transmission and flywheel housing as a unit.
17. Reverse the foregoing procedure to install the transmission.

Fig. 3 T.V. rod adjustment. 1956. Typical of 1957-62

1959-60

1. Disconnect battery.
2. On 1957-60, remove transmission filler pipe bracket bolt from right cylinder head.
3. Remove starter motor.
4. Slide filler pipe out of sleeve in transmission case.
5. Remove lower flywheel housing front cover.
6. Drain transmission at oil pan and flywheel.
7. Remove hoses from oil cooler and plug hose ends to prevent coolant leakage.
8. Remove propeller shaft.
9. Remove cross member under flywheel housing.
10. Disconnect speedometer cable.
11. Remove rods from side of transmission.
12. Remove four nuts from flywheel-to-drive plate screws.
13. Support rear of engine with jack.
14. With a separate jack, raise transmission just enough to take strain off rear engine support.
15. Remove rear engine support and cross member that carries support.
16. Remove flywheel housing-to-engine screws.

17. Remove transmission and flywheel housing as a unit. When transmission is removed from car, take out washer from pilot hole in crankshaft and four spacer washers from drive plate screws.
18. Reverse foregoing procedure to install transmission.

1961-62

1. Disconnect battery and raise car.
2. Remove starter motor and slush deflector.
3. Remove front and lower flywheel housing covers.
4. Drain transmission and torus cover.
5. Remove transmission filler pipe bracket bolt from right cylinder head.
6. Slide filler pipe out of sleeve in transmission.
7. Disconnect brake cables from parking brake relay lever. Remove retracting spring and remove relay from frame.
8. Remove propeller shaft.
9. Remove intermediate frame crossmember from below flywheel housing.
10. Disconnect speedometer cable.
11. Disconnect TV and manual rods.
12. Remove four nuts from flywheel-to-drive plate screws.
13. Support engine with jack under oil pan.
14. Raise transmission enough to take strain off rear engine support.
15. Disconnect rear engine mount at transmission extension housing.
16. Remove six screws and remove rear engine support from frame.
17. Disconnect oil cooler pipes from adapter on transmission case.
18. Remove six screws holding flywheel housing to engine.
19. Remove transmission and flywheel housing as a unit by moving assembly toward rear of car, disengaging flywheel housing from locating dowels on engine, and then tilting front of unit downward to lower it from car. Remove washer from pilot hole in crankshaft.
20. Reverse removal procedure to install transmission.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

To remove the differential carrier assembly, disconnect the rear universal joint and remove the axle shaft as described further on. Remove the cap screws holding the carrier to the axle housing and take out the carrier.

Note — Any service on the differential carrier should be made by replacement of the complete assembly. Cadillac does not recommend any disassembly or adjustments of this unit.

Note—In case of lubricant seepage between the differential carrier and the axle housing, first make sure that the cap screws are tightened to the recommended tension of from 30 to 35 pounds feet. If this does not stop the leakage, install an extra gasket, using a good sealing compound. The additional cushioning effect of the extra gasket will prevent further seepage.

AXLE SHAFT, REPLACE

1. Remove road wheel.
2. Remove two screws holding brake drum to axle shaft flange and remove drum.
3. Remove nuts and washers holding bearing retainer and backing plate to axle housing.
4. Install axle shaft puller on axle shaft studs and, using a slide hammer, remove axle shaft.

Service Note

Before installing an axle shaft after an oil seal has been replaced, inspect rear wheel bearings for loss of lubricant, since a leaky oil seal may have permitted differential lubricant to "wash out" grease in the sealed wheel bearing. A wheel bearing that spins freely indicates a lack of grease and should be replaced at the same time a new oil seal is installed.

BRAKE MASTER CYLINDER, REPLACE

1955

1. To remove the cylinder, remove splash shield from flywheel housing.
2. Disconnect brake line at front of master cylinder, and on 1954-55 models, loosen remote filler reservoir pipe fitting in master cylinder cover.
3. Depress brake pedal a few times to force all fluid from cylinder.
4. Disconnect pedal operating rod at clevis on brake pedal. Disconnecting at this point retains approximate adjustment.
5. Unfasten master cylinder from frame bracket and lift unit off car.
6. Install in the reverse order. Then fill reservoir with approved brake fluid and bleed system.

POWER BRAKE, REPLACE

1955

To remove the power brake unit, disconnect brake lines at power cylinder end plate. Loosen vacuum line hose clamp at check valve and slide hose off check valve. Remove three nuts and lockwashers from cylinder mounting bracket and remove unit from car.

Install the power brake unit in the reverse order of removal and bleed the system as outlined below.

1956

To remove the power brake unit, disconnect relay-to-unit rod at clevis. Disconnect relay rod from push rod. Disconnect both vacuum hoses from unit, and the hydraulic line at the outlet fitting. Remove screws and nuts from the mounting bracket and remove the power brake unit from the car.

Reverse the foregoing procedure to install the power brake unit and bleed the system as outlined below.

1957-58

1. To remove the power brake unit, disconnect remote filler tube from unit.
2. Disconnect vacuum inlet from unit.
3. Disconnect hydraulic fittings from unit and cap lines.
4. Remove four bolts securing unit to cowl and remove unit from car.
5. Reverse the above precedure, check fluid level and bleed system as outlined below.

1959-61

1. Disconnect hydraulic output line from master cylinder of power unit.
2. Disconnect vacuum and hydraulic hoses from power unit.
3. Unfasten power unit push rod from brake pedal relay lever.
4. Unfasten and remove power unit from cowl.
5. Reverse removal operations to install.

1962

1. Disconnect hydraulic lines from master cylinder on power unit. Cap line fittings to prevent dirt entering system
2. Disconnect vacuum hose from vacuum check valve on power unit.
3. Remove cotter pin and spring spacer that attach power unit push rod to brake pedal relay lever.
4. Unfasten and remove power unit from cowl.

5. Reinstall in reverse order of removal. *When installed, start engine and allow vacuum to build up before applying brakes.*

BLEEDING POWER BRAKE SYSTEM

1962

The master cylinder is self-bleeding and requires no bleeder fitting. However, the car must be on a level floor or have the front end lower than the rear.

Bendix Unit

1. Remove both master cylinder filler caps.
2. Connect bleeder hose to front reservoir.
3. Install solid filler cap on rear reservoir. *A solid filler cap can be made by welding the vent hole closed in any metal filler cap.*
4. Attach drain hose to bleeder fitting on each wheel cylinder.
5. Back off fitting ¾ turn and bleed fluid into a partially filled bottle of clean brake fluid until bubbles stop, then close fitting.

Delco Moraine Unit

1. Connect bleeder hose to front master cylinder reservoir.
2. Attach drain hose to bleeder fitting on each rear wheel cylinder.
3. Bleed wheel cylinders in a manner described above.
4. Connect bleeder hose to rear master cylinder reservoir and repeat procedure for front wheel cylinders.

1959-61

There is no bleeder fitting at the master cylinder, the unit being self bleeding. However, the car must be on a level floor or the front end lower than the rear. *Vacuum in the reserve tank should be exhausted by several pedal applications.*

If a pressure bleeder is not available, bleed the system by first filling the master cylinder reservoir with brake fluid. Then bleed the system at the wheel cylinders in the conventional manner.

1955 and 1957-58

Bleeding the system is accomplished in the same manner as for conventional bleeding as outlined in the *Hydraulic Brake System Chapter* except that the power brake cylinder is bled first by attaching the bleeder hose to the fitting on the end cap. Back off the fitting ¾ turn and depress the brake pedal until bubbles cease. Next, bleed the upper fitting on the end plate above the vacuum control valve housing. Then proceed with the wheel cylinders in the usual manner.

1956

Do not run the engine while bleeding brakes. The bleeding operation should be performed by bleeding the master cylinder (part of power brake unit) first. Fill the master cylinder with approved blake fluid. Attach bleeder hose to fitting on master cylinder, apply pressure to the brake pedal, back off fitting ¾ turn and depress brake pedal until bubbles cease. Close bleeder valve before releasing pressure on brake pedal. Then proceed to bleed the wheel cylinders in the usual manner.

Front End and Steering Section

WHEEL ALIGNMENT

1961-62

Camber Adjustment—Adjustment is made at the camber eccentric located in the steering knuckle upper support, Fig. 1. The upper ball joint stud fits through the camber eccentric and knuckle support. Turning the eccentric repositions the upper ball joint stud.

To adjust camber, loosen the ball joint stud nut one turn and tap bottom of stud with soft mallet to loosen eccentric. Using a suitable wrench, Fig. 2, turn the eccentric as required to obtain the camber specifications listed in the *Wheel Alignment* chart. The final position of the stud should be in the rear portion of the camber eccentric in order to keep steering angle correct. After proper adjustment has been established, torque stud nut to 50-65 ft. lbs.

Fig. 1 Camber adjustment eccentric. 1961-62

Service Note

If the camber eccentric is too tight to be adjusted a tool can easily be made by cutting a piece of 7/16″ diameter steel rod about 20″ long, chamfering it on one end and rounding it off on the other end.

If the eccentric must be freed for a camber adjustment, position the car on a wheel alignment machine, backing off the self-locking nut on the ball joint stud one turn, and thread a standard nut halfway on the stud. Insert the rounded end of the tool inside the nut and against the bottom of the stud. Then pound on the end of the tool with a heavy hammer to break the camber eccentric loose, Fig. 2A.

In cases where the eccentric is to be removed but comes loose from the stud instead of the knuckle, place a washer against the bottom of the eccentric and drive the eccentric out from below, using the same tool as described above. When the eccentric must be removed in this manner, inspect it for damage and replace if necessary.

Caster Adjustment—Adjustment is made by turning the retaining nuts on the forward ends of the tie-struts at the frame front crossmember, Fig. 3. To gain access to the retaining nuts, it is necessary to remove the splash shield.

Proper caster adjustment is obtained by shortening or lengthening the struts between the lower suspension arms and the frame front crossmember. To provide more negative caster, lengthen the struts by loosening the front bushing retaining nuts and tightening the rear bushing retaining nuts. One turn of the nuts results in approximately ½° change in caster.

To provide more positive caster, shorten the struts by loosening the rear bushing retaining nuts and tightening the front bushing retaining nuts.

After proper adjustment has been made, tighten front retaining nuts to 55-70 ft. lbs., being sure to hold the rear nut with a wrench so as not to disturb the adjustment.

Toe-In Adjustment—Toe-in is adjusted by turning the tie rod adjusters at the outer ends of each tie rod after loosening the clamp bolts. (Both right and left pivot ends have right-hand threads.) Be sure to turn both adjusters an equal amount so that the relation of the steering gear high spot to the straight ahead position of the front wheels will not be changed.

When adjustment has been completed according to the specification listed in the *Wheel Alignment* chart, tighten nuts on clamp bolts to 15-20 ft. lbs. torque.

Service Note

Make certain that both inner and outer tie rod ball pivots are centered in their respective housings prior to tightening the tie rod adjusting clamps.

If the tie rods are not properly positioned, a binding condition may occur, resulting in poor return of wheels

to the straight ahead position.

Each tie rod should be checked after adjustment by grasping the center of the tie rod and rotating it fore and aft. The movement should be equal in both directions. If not, it indicates that the pivot studs are not properly positioned.

1957-60

Caster & Camber—These adjustments are made by adding or removing shims between the upper suspension arm mounting shaft and the frame mounting bracket.

To change caster, add or remove the correct thickness of shims at one of mounting bolts. Addition of shims at the front bolt or removal of shims at the rear bolt will decrease positive caster. Removal of shims at the front bolt or addition of shims at the rear bolt will increase positive caster.

To change camber, add or remove shims of equal total thickness at both mounting bolts. Addition of shims at both bolts will decrease positive camber. Removal of shims at both bolts will increase positive camber.

The shims for adjustment are available in three thicknesses: .0149", .0418" and .1046". The shims will change caster and camber by the following amounts:

Shim Size	Caster Change (Shim at one bolt)	Camber Change (Shim at both bolts)
.0149"	1/6°	1/15°
.0418"	½°	1/5°
.1046"	1 1/6°	½°

Changing shims at one bolt to correct caster will affect camber slightly. If a large caster change is made, the resulting camber change should be taken into consideration.

The following table gives the amount of change in camber when adding shims to the front or rear bolts to change caster:

Shim Size	Camber Change When Shims are Changed At: Front Bolt	Rear Bolt
.0149"	0°	1/15°
.0418"	1/60°	1/5°
.1046"	1/30°	1/2°

When possible, make caster adjustments by changing shims at the front bolt because the resulting camber change will be small, as can be seen in the table above.

If more than ¼" total thickness of shims are necessary to bring suspension within specifications, check for bent or damaged parts.

To adjust caster and camber, loosen the upper suspension arm mounting bolts and add or remove shims as required. Then tighten the mounting bolts 130-140 lb. ft.

NOTE: In order to avoid pulling to the right on high crowned roads, it is necessary to adjust the camber so that the left wheel is ¼° to ½° more positive camber than the right wheel.

Toe-In Adjustment—This adjustment is accomplished by turning the tie rod adjusters at the outer ends of each tie rod after loosening clamp screws. Turning the adjusters in the direction the wheels revolve when going forward decreases toe-in.

Fig. 2A Steel rod used for loosening stuck camber eccentric. 1961

Fig. 2 Adjusting camber. 1961-62

Be sure to turn both adjusters an equal amount so that the relation of the steering gear high spot to the straight ahead position of the front wheels will not be changed. When adjustment has been completed, tighten all clamp screws, *being sure open side of clamp is over open side of adjuster before tightening clamp.*

1955-56

Caster Adjustment —Loosen the clamp screw at the upper end of the steering knuckle support. Turn the eccentric bushing in complete turns only until correct caster is obtained. Tighten the clamp screw.

If it is necessary to secure a greater range of adjustment than is provided by the eccentric bushing, this can be made by removing the lower control arm inner shaft from the frame and turning the shaft so that the threaded ends move the entire suspension arm assembly forward or rearward as required. Screwing the shaft rearward moves the control arms forward and increases the amount of positive caster.

Camber Adjust—Loosen the clamp screw at the upper end of the steering knuckle support. Rotate the eccentric bushing not more than ½ turn in either direction, otherwise the caster adjustment will be affected. If correct camber adjustment cannot be obtained within ½ turn of the eccentric bushing, look for bent suspension parts.

Toe-In Adjust—This adjustment is made in the same manner outlined for 1957-60 models.

WHEEL BEARINGS, ADJUST

1960-62

When adjusting the front wheel bearings, raise the front of the car and make sure that the wheel is completely seated on the spindle. Tighten the adjusting nut to 30 ft. lbs. torque and rotate the drum to be sure all parts are properly seated and the threads are free. Then back off the nut ¼ turn. If the cot-

Fig. 3 Adjusting caster. 1961-62

ter pin cannot be installed in either of the two available holes in the spindle with the nut in this position, loosen the adjusting nut until the cotter pin can be installed. The wheel should spin freely.

1955-59

Procedure for adjusting wheel bearings is similar to that outlined for 1960 models except that the adjusting nut should be tightened to 25 ft. lbs. on 1959 and 16-17 ft. lbs. on earlier models. After nut has been tightened to the proper torque, back it off and retighten to 4 ft. lbs. If the cotter pin cannot be installed in this position, tighten adjusting nut further but do not exceed 12 ft. lbs.

Fig. 4 Front suspension. 1961-62

CHECKING BALL JOINTS FOR WEAR

To check upper ball joint for wear, disconnect it from the steering knuckle. Then using the regular ball joint stud nut and a second nut as a lock nut, turn the joint in its socket with a torque wrench. If the torque is outside the range of 2 to 4 ft. lbs, replace the ball joint.

The lower ball joint is designed to turn freely in its socket and cannot be checked with a torque wrench. It should be checked by noting the amount of free play as the joint is worked up and down in its socket. Replace joint if free play exceeds $\frac{1}{16}$".

1961-62 FRONT END

All lubrication fittings have been eliminated from this suspension, Fig. 4. The control arms are rubber bushed and the ball joints are packed with a special lubricant and sealed. However, service plugs are provided in the ball joint covers so that the joints may be repacked when necessary and also in the event a seal should become damaged and require replacement.

Shock Absorber

The shock absorbers are removed through the bottom of the lower control arm after unfastening it at the top and bottom.

To install, place the retainer and rubber grommet on the upper stem and fully extend the shock absorber rod. Insert the shock absorber up into the coil spring and guide the stem through the tower in the crossmember. Then place the lower end in position on the lower control arm. Install bolt, washer and nut and torque nut to 90-110 ft. lbs. Fasten shock absorber at top.

Tie-Strut & Bushings

Raise car and jack up under frame side rails. Remove splash shield and disconnect stabilizer link from lower control arm on side tie-strut is to be removed. Remove strut and bushings as suggested by Fig. 4. Then replace as follows:

1. Insert spacer in rear bushing and install bushing and spacer in frame through rear side of crossmember.
2. Install nut on tie-strut and run nut to bottom of thread.
3. Install rear bushing retainer on strut with concave side toward nut.
4. With strut held in horizontal position, install threaded end of strut through rear bushing in frame crossmember.
5. Install front bushing on end of strut and slide bushing into position in frame crossmember. Front bush-

ing should lock in rear bushing.
6. Install front bushing retainer on threaded end of strut with flat side against bushing. Start front nut on end of strut but do not tighten.
7. Secure opposite end of strut to lower control arm and torque bolts to 30-40 ft. lbs.
8. Connect stabilizer link.
9. Lower car and with car weight on all four wheels, tighten front nut to 55-70 ft. lbs.
10. Tighten rear nut, compressing bushing until retainer bottoms on metal spacer in bushing.
11. Adjust caster as outlined previously.
12. Install splash shield.

Upper Ball Joint & Seal

1. Remove nut from ball stud.
2. Scribe a mark on camber eccentric and steering knuckle to facilitate alignment on installation.
3. Strike bottom of ball stud with soft mallet to break it loose from knuckle.
4. Raise upper control arm and remove ball joint from knuckle.
5. Remove camber eccentric from joint stud with a suitable puller.
6. Remove seal. Clean pivot joint and stud with solvent. Inspect ball pivot for looseness or binding and replace joint if necessary.
7. Install new seal as outlined below.
8. With new seal installed, install camber eccentric on joint stud, aligning scribe marks on eccentric and knuckle.
9. Install a standard nut on joint stud and tighten nut until camber eccentric locks in knuckle. Then remove standard nut and install special lock washer and locking nut and torque nut to 50-65 ft. lbs.

Installing Joint Seal

1. Turn new seal inside out.
2. Place snap ring inside seal just over bottom hole.
3. Press in on bottom of seal until snap ring seats in groove around hole.
4. Apply a small amount of grease around hole in seal and install seal on joint stud.
5. Unroll seal until lip engages in recess around joint housing.
6. Allow air to enter seal by momentarily prying lip of seal away from joint housing with a small screwdriver.
7. Squeeze seal, sliding snap ring end up on stud.
8. Lubricate outer surface of seal with vaseline and install garter spring on seal. Be sure spring secures lip of seal in recess all around joint housing. *If spring should separate where it is joined together, join them together and lock by twisting male end counterclockwise.*
9. After installing ball joint on car as outlined above, pry service plug from ball joint cover and discard plug. *With a suitable packing gun filled with the special lubricant for this purpose, fill joint with the lubricant, but do not permit the seal to balloon as this will shorten the seal's life. Under no circumstances should any grease but the type recommended be used in these ball joints for to do so will cause premature failure.*
10. Install new service plug in joint cover.

Fig. 5 Front coil spring suspension. 1957-60

Lower Ball Joint

When disconnecting the front lower suspension arm ball joint from the steering knuckle, support the lower arms with jack stands positioned 2" inboard from the ball joint before attempting to remove the lock nut from the ball joint stud.

Remove the lock nut and install a standard nut on the joint stud, running the nut to within two threads of the knuckle support. Raise car slightly off the jack with a hydraulic jack and strike the knuckle support with a heavy hammer to break the joint loose.

In the event the tapered end of the stud is not wedged tightly in the lower knuckle support, the jack stands will prevent the lower arm from being forced down by the coil spring when the locking nut is removed.

1957-60 FRONT END

Shock Absorber, Replace

Raise hood and remove shock absorber upper retaining nut, retainer and rubber grommet at frame mounting bracket. Remove two screws holding shock absorber to lower spring seat. Remove shock absorber from spring.

Reverse procedure to install shock absorber, Fig. 5.

Upper Ball Joint, Replace

Raise car and place stand jacks under lower suspension arms. Remove wheel. Remove nut from ball stud. Strike steering knuckle with a hammer in area of

stud to loosen joint. Raise upper suspension arm so that joint clears knuckle. With a $\frac{5}{16}$" drill, drill out all ball joint rivets. Then remove ball joint.

Install new ball joint on upper suspension arm with bolts, nuts and lockwashers provided in service replacement kit. Tighten nuts to 20-25 lb. ft. Position ball joint stud in knuckle, install nut and tighten to 50-60 lb. ft. Install cotter pin.

Lower Ball Joint, Replace

Raise front of car and place jack stands under forward portion of frame side members. With a jack under spring seat, raise lower suspension arm about one inch (measured at its outer end). Remove nut from ball joint stud. Strike steering arm with a hammer to break joint loose. Remove retaining nuts and bolts and raise lower suspension arm to allow ball joint to be removed.

To install, position ball joint on suspension arm and tighten nuts to 35-40 lb. ft. Head of bolt should be under joint flange. Position joint stud in steering arm mounting hole. Lower jack to allow joint to seat itself in steering arm, and remove jack. Install ball joint nut, tighten to 50-60 lb. ft. and install cotter pin.

1955-56 FRONT END

Steering Knuckle, Remove

1. Lift front end of car from floor with jack.
2. Remove front wheel, hub, brake drum and wheel bearings.
3. Remove brake dust shield with brake shoes attached. Do not damage the hydraulic line which does not have to be removed in this operation.
4. Drive lock pin from steering knuckle support, Fig. 3.
5. Remove dust caps at upper and lower knuckle pin holes, and remove steering knuckle and thrust bearing from knuckle support.

Kingpins, Install

1. If these bushings are to be replaced, slot them lengthwise with a hacksaw and drive them out with a chisel.
2. Press new bushings into steering knuckle, being sure that the oil hole in each bushing lines up with the oil hole in the knuckle. Reaming of bushings is not necessary provided care is used when making the installation.

Steering Knuckle, Install

1. Assemble steering knuckle to support with thrust bearing in position between support and lower face of steering knuckle.
2. Drive lock pin in from front of support.
3. Use new plugs at both ends of kingpin.
4. Install grease fittings and lubricate thoroughly.
5. Install brake assembly, lubricate and adjust front wheel bearings after installing wheel.

Knuckle Support, Remove

1. Remove steering knuckle as outlined previously.
2. Place jack under lower control arm to support coil spring while disconnecting knuckle support.
3. Remove nut from rear end of upper pivot pin.
4. Remove threaded pivot pin and rubber dust seals.
5. Remove nut from rear of lower pivot pin.
6. Remove lower pivot pin and rubber dust seals.
7. Place support in vise and loosen clamp screw at upper end of knuckle support.
8. Remove upper and lower bushings from support.

Fig. 6 Front suspension, 1955-56

Knuckle Support, Install

1. Install eccentric bushing in knuckle support so that it is centralized and install clamp screw lightly.
2. Install bushing in lower end of knuckle support, tightening bushing firmly so that there is no clearance between bushing shoulder and knuckle support.
3. Install lower end of knuckle support, with bushing, between outer ends of lower control arm. Install rubber dust seals between control arm and support on both sides.
4. Install threaded pivot pin, holding support so that space between support and arms is equal on both sides.
5. Install upper end of support in position between ends of upper control arms and install rubber seals.
6. Install upper pivot pin and nut with upper end of support centralized between ends of upper control arms.
7. Install steering knuckle and adjust caster, camber and toe-in.

HORN SOUNDER

1962

1. Pry off cap on steering wheel and horn control shroud.
2. Disconnect horn contact wire from top of steering shaft.
3. Remove upper steering shaft nut.
4. Lift horn control shroud and switch from steering wheel.
5. Remove four screws from retainer on bottom side of wheel shroud. *To facilitate disassembly, press down on horn contact plate when removing screws to relieve spring pressure and prevent damage to retainer.*
6. Remove retainer, rubber cushion, contact plate, spring and insulator, spring retainer and horn ring insulator.
7. Reverse above procedure to install.

1961

1. Pry off cap on steering wheel hub.
2. Remove two screws from underside of wheel rim (one at outside end of each spoke).
3. Remove two Allen head screws retaining hub to steering wheel and remove hub and upper half of spoke with horn bars.
4. The horn switches may be removed from lower section of spoke by removing one screw retaining each switch in spoke.
5. Reverse foregoing procedure to install.

1960

1. Remove two screws from underside of steering wheel rim.
2. Pry off cap on steering wheel hub.
3. Remove two smallest screws (farthest from center) from hub and remove lower sections of horn control housing.
4. Disconnect horn wire from center of hub.
5. Remove two remaining screws from wheel hub and remove upper section of horn control housing.
6. To remove horn switches from upper section, disconnect horn wire and remove two screws from each switch.
7. To install, reverse above procedure.

1959

1. Disconnect horn wire from terminal on neutral safety switch beneath instrument panel on steering column.
2. Remove Phillips head screw securing horn ring cap and remove cap.
3. Remove horn ring contact spring and retainer by depressing retainer and turning until retainer and spring snap out.
4. Remove two Allen screws, one on under side of each spoke at steering column and remove spoke ring covers.
5. To install, reverse above procedure.

1956-58

1. Disconnect horn wire from terminal beneath instrument panel on steering column.
2. Loosen Allen head screws on underside of horn ring, one on each side of turn signal carrier, and remove horn ring.
3. After installing horn ring, tighten Allen screws on underside of ring. Then depress horn ring several times to make certain that it is properly seated on wheel spokes and retighten set screws.

1955

1. Disconnect horn wire from terminal at lower end of steering column.
2. Depress horn button and turn in either direction until locking ears are released and remove button.
3. Remove horn button spring and steering wheel nut. Then remove horn ring retainer, cushion and horn ring.
4. To install, reverse above procedure.

STEERING WHEEL

1961-62

1. Remove cap from steering wheel hub by prying it off.
2. Disconnect horn wire from steering shaft.
3. Remove upper steering shaft nut.
4. On 1962, lift out horn control shroud and switch assembly.
5. On 1961, remove two screws securing hub to steering wheel.
6. Scribe an alignment mark on wheel hub and on end of steering shaft to use for alignment on installation.
7. Use puller to remove wheel.

1955-60

After removing horn sounding mechanism as outlined above, remove steering wheel hub nut and use a puller to remove wheel.

Worm Bearing Adjustment—Disconnect steering connecting rod at pitman arm. Turn steering wheel to either right- or left-hand stop. Then check load to pull steering wheel back to a point not less than 90° from the straight-ahead position of the steering wheel. The load should not be less than one lb. or more than 1⅛ lb. Load is checked with a spring scale hooked to the rim of the steering wheel. To adjust, loosen lock nut and turn the worm bearing adjusting screw as required. Tighten the lock nut and recheck the adjustment.

Cross Shaft End Play—Turn the steering wheel about 90° each way through center. The pull through center should be between 1½ and 2 lbs. If an adjustment is required, loosen the lock nut and turn the cross shaft adjusting screw in the direction required to obtain the desired result. Tighten the lock nut when the adjustment is correct and recheck the adjustment.

Install the steering connecting rod. The end nut on the pitman arm ball stud should be turned up tight and backed off ⅞ to one turn.

POWER STEERING, REPLACE

1962

1. Disconnect pressure and return line hoses at rear of pump reservoir. Cap pump fittings to prevent drainage of fluid from pump.
2. Jack up car and place jack stands near outer ends of lower suspension arms.
3. Disconnect pitman arm from steering gear.
4. Remove screw that holds flexible coupling to upper steering shaft.
5. Remove three screws that hold gear housing to frame and remove gear.
6. Reverse foregoing procedure to install the steering gear. Tighten gear housing-to-frame screws to 45 ft. lbs. Tighten pitman shaft nut to 115 ft. lbs. Fill reservoir to level mark or 1½" from top of reservoir neck. Replace filler cap, start engine and idle for three minutes, then check for leaks in reservoir shell.
7. Any air trapped in the system should be bled out by running engine at a fast idle for about two minutes. Turn wheels occasionally from right to left without hitting the stops. Recheck fluid level after bleeding system.

1956-61

1. To remove steering gear, remove tank cover from pump and discard gasket.
2. Syphon all fluid from tank.
3. Disconnect pressure and return line hoses at tank and pump, and cap ends to prevent fluid drainage.
4. Raise front end of car and place stand jacks near outer ends of lower suspension arms.
5. Disconnect pitman arm from steering gear.
6. Remove upper flange-to-shaft retaining screw.
7. Unfasten and remove gear housing from frame.
8. Reverse the foregoing to install the gear. Tighten upper flange-to-shaft retaining screw to a torque of 25-30 lb. ft. After installing the gear, check the flexible coupling for distortion. If distorted, correct as outlined for 1955 steering gear.

1955

1. To remove steering gear assembly, disconnect hydraulic hoses from valve body on gear housing. Cap ends of hoses to prevent loss of oil.
2. Remove return port (large) fitting from valve body.
3. Raise front of car and place stand jacks near outer ends of lower suspension arms.
4. Disconnect pitman arm from drag link.
5. Remove lower flange-to-coupling screws.
6. Scribe marks on flange and coupling to assure correct positioning of steering wheel at assembly.
7. Unfasten gear housing from frame and remove gear housing.
8. After installing the gear in the reverse order of its removal, check the flexible coupling for distortion. The coupling must rest in a flat plane with no visible bend or twist. If it is distorted, remove lower steering column cover and lower clamp-to-jacket screw. Then loosen the steering jacket clamp screws at the instrument panel and slide the complete steering jacket up or down as required. Redrill the lower clamp and jacket, if necessary, to reinstall screw.

Instruments, Windshield Wiper and Radio

INSTRUMENT CLUSTER

1955

1. Remove 2 screws holding triangular steering column cover plate to toe riser and leave third screw in position.
2. Remove 5 screws holding square cover plate to toe riser.
3. Remove brake stop light switch.
4. Disconnect speedometer cable.
5. Remove lower steering column cover and transmission dial indicator pointer.
6. Disconnect vent cables from firewall and vent.
7. Remove U clamp nuts and lower steering column.
8. Disconnect trip odometer reset stem.
9. Remove 3 cluster mounting screws.
10. Pull cluster out far enough for access to defroster and heater control arm brackets and remove these parts.
11. Cluster may now be pulled out for further service.

1956

1. Disconnect speedometer cable.
2. Remove lower steering column cover and transmission dial indicator pointer.
3. Disconnect vent cables from firewall and vent.
4. Remove U clamp nuts and lower steering column.
5. Disconnect trip odometer reset stem.
6. Remove 4 cluster mounting screws and pull cluster out far enough to gain access to defroster and heater control arm brackets and remove these parts.
7. Cluster may now be pulled out for further instrument service.

1957

1. Disconnect speedometer cable.
2. Remove lower steering column cover and transmission dial indicator pointer.
3. Remove U clamp nuts and lower steering column.
4. Disconnect trip odometer reset stem.
5. Remove 4 cluster mounting screws.
6. Cluster may now be pulled out partially for further instrument service.

1958

1. Remove lower steering column cover and transmission dial indicator pointer.
2. Remove U clamp nuts and lower steering column.
3. Remove odometer reset stem, knob and retaining nut.
4. Remove 4 cluster mounting screws.
5. Remove 2 screws from base of heater and fresh air or Air Conditioning control panels.
6. Cluster may now be partially removed for further instrument service.

1959

1. Disconnect battery ground cable.
2. Remove lower steering column cover and Hydra-Matic dial indicator pointer.
3. Remove steering column U clamp nuts and lower steering column.
4. Remove odometer reset stem, knob and retaining nut and disconnect speedometer cable.
5. Separate upper instrument cover from lower panel (6 screws).
6. Raise upper panel as high as possible to gain access to and disconnect necessary connectors linking upper cover to lower panel.
7. Unhook upper cover hooks from cowl retainers.
8. Remove upper cover with instrument cluster.
9. Separate cluster from upper cover (4 nuts) and remove instruments as required.

1960

1. Disconnect battery ground cable.
2. Remove lower steering column cover and Hydra-Matic pointer.
3. Remove 6 screws retaining panel cover to lower instrument panel.
4. Raise front edge of cover and insert wood block between cover and lower panel to provide access to components.

1961

1. Disconnect battery ground cable.
2. Remove six screws retaining upper panel cover to lower panel.
3. Raise upper panel high enough to disconnect multiple connector for map light and Guidematic (if equipped).
4. Pull cover to unhook upper cover hooks from cowl retainers and remove cover.
5. Disconnect odometer reset cable and speedometer cable.
6. Disconnect all cluster bulbs and fuel and temperature gauge wires from rear of cluster.
7. Disconnect two connectors from lighting switch.
8. Remove two screws and one bracket (above radio) that hold bezel to instrument panel.
9. Remove nut on left side of bezel near headlight switch that holds bezel to instrument panel and remove bezel.
10. Remove cluster (2 screws each side).

1962

1. Disconnect battery ground cable.
2. Remove five screws retaining upper panel cover to lower panel.
3. Raise upper panel cover high enough to disconnect three-way connector for map light and three-way connector for Guide-Matic phototube unit (if so equipped).
4. Pull cover rearward to disengage hooks at front of cover from retainers on cowl and remove upper cover.
5. Remove radio knobs, springs and speaker and tone control rings.
6. Remove retaining nut from manual radio selector control shaft.
7. Disconnect one six-way wire connector and one single connector from headlamp switch. If equipped with fog lamps, disconnect one three-way connector also.
8. Disconnect light bulb socket and feed wire connector from clock.
9. Remove two bezel retaining nuts near headlamp switch.
10. Remove bezel retaining screw and nut near clock.
11. Remove screw holding bezel-to-cowl brace.
12. Disconnect gauge wires from back of fuel and temperature gauges.
13. Disconnect speedometer cable.
14. Remove cluster bulb sockets.
15. Disconnect odometer reset cable from lower flange of instrument panel.
16. Remove cluster (4 screws).

Service Note

If either or both fuel and temperature gauges are to be removed, it is only necessary to take off the upper instrument panel cover.

WINDSHIELD WIPER

1955-58

The transmission cables are tensioned by spring-loaded pulleys. Tight cables cause slow wiper operation. Loose cables cause blade slap or over-travel at end of stroke. If either of these conditions exist, readjust cable tension as follows:

Remove wiper arm. Press in on end of shaft to unlock spring-loaded pulleys and hold momentarily. Then release. This automatically sets cable tension.

To remove the motor, remove the screws which attach the motor to the support and disengage the motor from the auxiliary drive assembly. Disconnect the vacuum hoses and control cable from the motor. Unfasten and remove the motor.

1959-60

1. To remove wiper motor, disconnect cable from battery.
2. Disconnect multiple connectors and washer hoses at wiper unit.
3. Remove air intake grille.
4. Disconnect wiper unit from transmission control arms at wiper unit.
5. Remove distributor cap.
6. Unfasten wiper unit by removing screws (4) through ventilator grille opening.

1961-62

1. Disconnect battery ground cable.
2. Disconnect multiple connectors and washer hoses at wiper unit.
3. Disconnect wiper ground strap from body.
4. Remove air intake grille.
5. Remove nut retaining upper control arm to shaft.
6. Remove screw securing lower arm to unit and remove arm.
7. Remove upper crank arm from motor shaft and remove boot from shaft.
8. Remove four screws through air intake grille opening and remove wiper assembly from under hood.

RADIO REMOVAL

1955

1. Disconnect antenna lead plug from left side of radio.
2. Disconnect rear speaker wire from connector at top of glove box.
3. Disconnect front speaker wire at right side of radio.
4. Disconnect ignition lead (black) wire at fuse connector.
5. Remove antenna control knob, spring and tone control ring from right shaft. Following same procedure, remove volume control knob and sensitivity ring from left shaft.
6. Remove hex nut control escutcheon marked "tone". Following same procedure, remove hex nut escutcheon marked "sensitivity".
7. Remove mounting screws and washers from mounting bracket to radio.
8. Remove radio from under panel. Disconnect dial light feed wire (brown) at connector.
9. Disconnect 3 vacuum antenna hoses from clip and nipples on top of radio.
10. Remove dial light from top of radio chassis.

1956

1. Disconnect radio lead (black) and antenna lead (brown) from fuse connectors.
2. Disconnect speaker unit black feed lead at connector at rear of radio.
3. Disconnect 2 shielded bayonet connections from speaker.
4. Disconnect antenna lead from right side of radio.
5. Remove manual selector knob, volume control knob and tone control ring from left shaft.
6. Remove hex nuts retaining shafts and mounting screw from radio mounting bracket.
7. Remove radio through glove compartment, disconnecting 2 dial lights from top of radio and dark green and dark blue leads from plastic connectors.

1957

1. Remove glove compartment.
2. Disconnect radio lead (black) from fuse connector.
3. Disconnect front speaker feed leads (black) at connector for speaker.
4. Disconnect shielded bayonet connection from power unit.
5. Disconnect antenna motor lead (brown) from fuse connector.
6. Disconnect rear speaker lead (green) from harness connector.
7. Remove antenna connectors at bottom left rear of radio.
8. Remove control knobs and tone control ring from left shaft.
9. Remove hex nuts retaining shafts and mounting screw from radio mounting bracket.
10. Remove radio through glove compartment opening, disconnecting 2 dial lights from top of radio.

1958 Tubes and Vibrator

It is possible to remove and install all radio tubes and the vibrator without removing the radio from the car by the following procedure.

1. Remove heater crossover duct and rubber connector. Tubes and vibrator in the radio section are now accessible from the instrument panel. To remove, reach up and pull out tube sockets.
2. Remove 4 screws accessible through glove box, securing bottom cover plate to tuner section.
3. Pull down on right side of plate and remove by pulling to right. Tubes in the tuner section are now accessible for removal and installation through glove box.

1958 Radio Unit

1. Remove glove box.
2. Disconnect front and rear speaker leads.
3. Disconnect antenna lead.
4. Disconnect multiple connector from tuner section of tuner and audio unit.
5. Remove control knobs and tone control rings.
6. Remove retaining nuts from selector and volume control shafts and remove speaker and tone escutcheons (a special wrench, Tool No. J-6968, is available for removing these nuts).
7. Remove two nuts securing radio to mounting brackets under instrument panel.
8. Remove tuner and audio unit through glove box door opening and, at same time, disconnect light from top of tuner section.

1959-60

1. Working through the glove compartment, disconnect front and rear speaker leads.
2. Disconnect antenna lead.
3. Disconnect multiple connector from radio.
4. Remove knobs, springs and speaker volume and tone control rings.
5. Unfasten radio from mounting bracket under instrument panel.
6. Remove manual selector and volume control shafts.
7. Remove radio through glove compartment.

1961

1. Disconnect battery ground cable.
2. Remove upper instrument panel cover and bezel as outlined previously.
3. Disconnect speaker leads.
4. Remove three screws retaining radio mounting panel to heater vent control bezel.
5. Remove screw retaining radio to right and rear mounting brackets and lift radio with bezel from instrument panel.

1962

1. Remove upper instrument panel cover and bezel as outlined under *Instrument Cluster*.
2. Remove bezel-to-cowl brace.
3. Remove light bulb socket from top of radio and disconnect front and rear speaker connectors.
4. Remove bolt securing right side of radio to instrument panel.
5. Remove retaining nut from volume control shaft.
6. Remove screw securing radio to rear support bracket.
7. Move radio slightly forward until volume control ferrule threads clear mounting bracket. Then lift radio from panel sufficiently to gain access to electrical connectors.
8. Disconnect antenna lead-in cable and four-way electrical connector.
9. Disconnect foot control unit from bottom of radio (if so equipped).
10. Remove radio.

①—V8 cylinder numbering (front to rear): Left bank 1–3–5–7, right bank 2–4–6–8.
②—First short vertical line on flywheel clockwise from timing ball.
③—Second line before "O" mark on timing tab on front cover. Cars with two 4-barrel carburetors, use sixth line before "O" mark.
④—Turn adjusting screw in (clockwise) until engine misfires. Then turn screw ½ turn in opposite direction.
⑤—New points .019", used .016".
⑥—Both breakers 33–34°.

VALVE SPECIFICATIONS

★Adjust hydraulic lifters by tightening rocker arm stud nut just to the point where all lash is eliminated. Then turn nut the additional turns listed. See Valves Adjust text for details.

①—Fit rings in tapered bores the clearance listed in tightest portion of ring travel.
②—Piston should pass on a .002″ feeler with light pressure, and lock on a .003″ feeler.
③—No. 1, 2.6835—2.6845. No. 2, 2.7145—2.7155. No. 3, 2.7455—2.7465. No. 4, 2.7765—2.7775.
④—No. 1, 2.6856. No. 2, 2.7166. No. 3, 2.7478. No. 4, 2.7778.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

Engine Section

ENGINE, REPLACE

Chevrolet & Corvette

In addition to the usual items such as radiator, hood, fuel and electrical lines, and linkage, it is necessary to perform the following operations:

1. On V8s, remove oil filter, distributor cap and power steering and air suspension lines (if equipped).
2. Unfasten exhaust pipe from manifolds.
3. Disconnect speedometer cable and remove propeller shaft.
4. On 1955-57 Six, disconnect R.H. headlamp, parking lamp and horn wires and remove horns. Remove battery, its support and cables. Remove windshield wiper motor.
5. Attach a suitable lifting rig and unfasten all engine and transmission mounts. Then lift out engine and transmission as a unit.
6. Reverse above procedure to install.

Chevy II

In addition to the usual items such as radiator, hood, fuel lines, electrical wiring, and linkage, it is necessary to perform the following operations:

1. Disconnect exhaust pipe from manifold.
2. Disconnect clutch cross shaft bracket at frame, and disconnect clutch push rod, spring and pedal linkage.
3. On automatic transmission jobs, remove transmission oil filler tube and plug opening in transmission.
4. Remove rocker arm cover and road draft tube.
5. Install engine lifting tool in two cylinder head bolt holes and attach hoist.
6. Remove propeller shaft and plug end of transmission extension housing.
7. Disconnect steering linkage idler arm bracket from right side of frame, and lower linkage for clearance.
8. Remove engine rear mounting bolts.
9. Disconnect speedometer cable and transmission control rod linkage lower ends.
10. Loosen engine front mounting bolts.
11. Raise engine slightly and remove front engine mounts.
12. Remove transmission crossmember and free transmission rear mounting. *WARNING: Extreme care should be used while removing crossmember. Stand clear of it as it is possible, unless sufficient weight has been taken off the member, that the transmission extension and/or crossmember will be forced to swing suddenly downward when released.*
13. On 4-cylinder only, remove front crossmember.
14. Remove engine and transmission as a unit.

Cutaway view of Chevy II four cylinder engine. Design of six cylinder engine is similar

CYLINDER HEAD

Chevy II

1. Drain cooling system and remove air cleaner.
2. Disconnect choke cable, accelerator pedal rod at bellcrank on manifold, and fuel and vacuum lines at carburetor.
3. Disconnect exhaust pipe at manifold flange, then unfasten and remove manifolds and carburetor as an assembly.
4. Remove fuel and vacuum line retaining clip from water outlet and disconnect wire harness from temperature sending unit and coil, leaving harness clear of clips on rocker arm cover.
5. Disconnect radiator hose at water outlet housing and battery ground strap at cylinder head.
6. Remove spark plugs. On 6-cylinder engine, remove coil.
7. Remove rocker arm cover. Back off rocker arm nuts, pivot rocker arms to clear push rods and remove push rods.
8. Unfasten and remove cylinder head.
9. Reverse removal procedure to install

Fig. 1 Cylinder head tightening sequence. Chevy II four cylinder

Fig. 2 Cylinder head tightening sequence. Chevy II six cylinder

V8-265, 283, 327 engines

Fig. 3 Cylinder head tightening sequence. V8-265, 283, 327

head. Tighten attaching bolts in the sequences shown in Figs. 1 and 2 and to the torque listed in the *Engine Tightening Table.*

Chevrolet & Corvette

V8-265, V8-283, V8-327

1. Drain radiator and remove air cleaner.
2. Disconnect throttle rod from carburetor. On Powerglide or Turboglide models, disconnect lower transmission throttle lever rod.
3. Disconnect fuel, vacuum and automatic choke lines from carburetor.
4. Disconnect coil wires and remove distributor.
5. On overdrive models, disconnect kickdown switch wires from switch.
6. Remove spark plugs.
7. Remove water outlet hose and heater hose from intake manifold.
8. Remove temperature indicator unit from intake manifold.
9. Unfasten and remove intake manifold.
10. Remove fan belt.
11. Disconnect exhaust manifold from cross-over pipe and allow cross-over pipe to drop for clearance.
12. Remove heat control valve from right bank exhaust manifold.
13. Disconnect wires from generator.
14. Remove exhaust manifolds.
15. Remove choke heat tube and rocker arm covers.
16. Back off rocker arm nuts, pivot rocker arms to clear push rods and remove push rods. *Be certain that push rod seats on solid lifters do not come out of lifters with push rods. Snap push rod lower end to one side before lifting to break loose push rod from seat.*
17. Remove head bolts and lift off heads. *On 1960-62 models, be sure to note that the bolts in positions 17 and 14, Fig. 1, are shorter in length and must be installed in these positions upon reassembly.*
18. Reverse the above procedure to install the heads and tighten bolts in the sequence shown in Fig. 3. Torque head bolts 60-70 lb. ft., and intake and exhaust manifold bolts to 25-35 lb. ft.

V8-348 & V8-409

1. When removing right head on air conditioned cars, remove air compressor, mounting brackets and lines.
2. When removing left head on cars

V8-348 and V8-409. Note wedge-shaped combustion chamber formed in block and that underside of cylinder head is flat

Fig. 4 Cylinder head tightening sequence. V8-348, 409

with power steering, remove power steering pump or air suspension compressor, mounting brackets and lines.

3. Drain cooling system.
4. Remove air cleaner and disconnect choke and throttle rod.
5. Disconnect fuel and vacuum lines from carburetor.
6. Remove distributor and spark plugs.
7. Remove water outlet hose and heater hose from intake manifold.
8. Remove intake manifold.
9. Remove exhaust manifolds.
10. Remove generator.
11. Remove rocker arm covers, back off rocker arm nuts, pivot rocker arms to clear push rods and lift out push rods.
12. Unfasten and remove cylinder heads.
13. Reverse removal procedure to install the heads and tighten them in the sequence shown in Fig. 4 to a torque of 60-70 lb. ft. Tighten intake manifold bolts and the center bolts on exhaust manifolds to a torque of 25-35 lb. ft. Exhaust manifold end bolts to 18-22 lb. ft.

Chevrolet 6

1. Drain radiator, raise hood and remove air cleaner. Disconnect throttle and choke wires from carburetor.
2. Disconnect throttle rod from carburetor.
3. Disconnect gas and vacuum lines from carburetor.
4. Remove gas and vacuum line retaining clip from water outlet.
5. Remove manifold assembly.
6. Remove water outlet and thermostat from cylinder head.
7. Remove rocker arm cover.
8. Remove all spark plugs.
9. Detach coil and lay it down out of the way.
10. Remove push rod cover.
11. Disconnect oil line from rocker arm connector (none after 1957).
12. Remove temperature indicator element from cylinder head.
13. Remove rocker arm assembly.
14. Remove bolts and lift off cylinder head.
15. Reverse removal procedure to install the head and tighten bolts in the sequence shown in Fig. 5.

Chevrolet 6 cylinder engine

VALVES, ADJUST

Hydraulic Lifters

The following procedure, performed with the engine running should be done only in case readjustment is required.

1. After engine has been warmed up to operating temperature, remove valve cover and install a new valve cover gasket on cylinder head to prevent oil from running out.
2. With engine running at idle speed, back off valve rocker arm nut until rocker arm starts to clatter.
3. Turn rocker arm nut down slowly until the clatter just stops. This is the zero lash position.
4. Turn nut down ¼ additional turn and pause 10 seconds until engine runs smoothly. Repeat additional ¼ turns, pausing 10 seconds each time, until nut has been turned down the number of turns listed in the *Valve Specifications Chart* from the zero lash position.

Service Note

This preload adjustment must be done slowly to allow the lifter to adjust itself to prevent the possibility of interference between the intake valve head and top of piston, which might result in internal damage and/or bent push rods. Noisy lifters should be replaced.

Fig. 5 Cylinder head tightening sequence. Chevrolet six cylinder

1961 Service Note

There is an "Engine Date Stamp" located on a machined surface at the front of the cylinder block which denotes the month and day on which the engine was assembled.

V8 engines assembled on and after 1/23/61 (date stamped F-0123) and 1/30/61 (stamped T-0130) are equipped with short travel lifters similar to those used in 1960 and earlier models. Engines assembled before these dates have long travel lifters. Be sure to check the date stamp before adjusting valves on 1961 V8 engines.

Mechanical Lifters

With the engine warmed to operating temperature as described above, turn rocker arm stud nut (V8's) or adjusting screw (6's) as required to obtain the clearances given in the *Valve Specifications* table.

Engine lubrication, V8-265, 283, 327

Engine lubrication, V8-348 and V8-409

Fig. 6 Removing valve rocker arm stud

Service Note

To be sure that the valves and lifters function perfectly, it is strongly recommended that a vacuum gauge be used when making the adjustment on hydraulic lifter jobs. With vacuum gauge connected and engine idling, tighten each rocker arm nut until the *highest and steadiest vacuum is indicated on the gauge.*

VALVE ARRANGEMENT

Front to Rear

4 Cylinder ..... E-I-I-E-E-I-I-E
6 Cylinder ..... E-I-I-E-E-I-I-E-E-I-I-E
V8s ..... E-I-I-E-E-I-I-E

ROCKER ARM STUDS

Chevy II & V8's

Rocker arm studs that have damaged threads may be replaced with standard studs. If studs are loose in the head, oversize studs (.003″ or .013″) may be installed after reaming the holes with a proper size reamer.

1. Remove the old stud by placing a suitable spacer, Fig. 6, over stud. Install nut and flat washer and remove stud by turning nut.
2. Ream hole for oversize stud.
3. Coat press-fit area of stud with rear axle lube. Then install new stud, Fig. 7. If tool shown is used, it should bottom on the head.

ROCKER ARMS

Chevrolet 6

Sludge and gum formation in the rocker arms and shafts will restrict the normal flow of oil to the rocker arms and valves. Each time the rocker arm and shaft assemblies are removed they should be disassembled and thoroughly cleaned.

Fig. 7 Installing valve rocker arm stud

1. Remove the support bolts, hairpin locks, springs, rocker arms and supports.
2. Clean all sludge and gum formation from the inside and outside of the shafts and from the oil distributor to valve rocker shaft tube.
3. Clean oil holes and passages in the shafts and rocker arms.
4. Clean the rocker arm shaft oil connector assembly.
5. Inspect the shafts for wear. Check and the valve end of the rocker arms the fit of the rocker arms on the shafts for excessive wear.
6. There are three each of four different types rocker arms used—right and left hand exhaust and right and left hand intake as shown in Fig. 8. Each rocker arm carries an identification number and the following chart serves to identify them.

1955-57 Six Std. Trans.

No. on Rocker Arm	Type Rocker Arm	For Cylinder No.
9	L. H. Exhaust	1-3-5 Exhaust
0	R. H. Exhaust	2-4-6 Exhaust
3	L. H. Intake	2-4-6 Intake
4	R. H. Intake	1-3-5 Intake

Fig. 8 Layout of rear rocker arm and shaft parts. Chevrolet six cylinder

Fig. 9 Checking valve spring tension

1955-57 Six Auto. Trans. and All 1958-62 Chevrolet Six

No. on Rocker Arm	Type Rocker Arm	For Cylinder No.
7	L. H. Intake	2-4-6 Intake
8	R. H. Intake	1-3-5 Intake
3	L. H. Exhaust	1-3-5 Exhaust
4	R. H. Exhaust	2-4-6 Exhaust

7. One end of each rocker arm shaft is plugged. The open end of each shaft must be toward the center.

VALVES, REMOVE

1. Place cylinder head on its side and, with a suitable valve spring compressor, compress valve springs and remove valve keys.
2. Release compressor tool and remove spring caps, spring seats, oil seals, springs and spring dampers.
3. Remove valves from bottom of cylinder head and place them in a rack or board with numbered holes so they will be in proper sequence for inspection and assembly.
4. Remove water outlet and thermostat, then thermostat housing.

VALVE GUIDES

Chevy II & V8's

Excessive valve stem-to-guide clearance will cause lack of power, rough idling and noisy valves, and may cause valve breakage. Insufficient clearance will result in noisy and sticky functioning of valves and disturb engine smoothness of operation.

Valve stem-to-guide clearances are listed in the *Engine Valve Specifications* table. By using a micrometer and a suitable telescope hole gauge, check the diameter of the valve stem in three places (top, center and bottom). Insert telescope hole gauge in valve guide bore, measuring at the center. Subtract the highest reading of valve stem diameter from valve guide bore center diameter to obtain valve-to-guide clearance. If clearance is not within specified limits, use the next oversize valve and ream bore to fit. Valves with oversize stems are available in .003", .015" and .030".

Chevrolet 6

Clean the valve guides with a wire guide brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Check the clearance between valve stems and guides carefully. The standard clearances are given in the *Valve Data* chart.

Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Valve stem-to-guide clearance may be checked with special "GO" and "NO-GO" gauges. Lacking these, an alternate method is to take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the guides that are worn as indicated by this test. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, it is an indication that the old valve stem is worn and a new valve must be installed.

To remove the old guides, place the cylinder head on the table of an arbor press and, with a suitable piece of round stock, press out the guides.

Special drivers having stop collars are available to install the new guides to the correct position. After the guides are installed, they should be finish reamed with hand reamer.

Fig. 10 Checking valve spring installed height

VALVE SPRING TESTING

Wash all springs with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 9, and according to the specifications given in the *Valve Data* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 10. If the assembled height is greater than the dimension given in the *Valve Specifications Chart*, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately 1/16" to 3/32", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are

Fig. 11 Checking valve seat concentricity with dial gauge

required to restore the correct valve spring installed height, *the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.*

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. This condition leads to premature breakage, burning and pre-ignition due to heat localizing on this knife edge. If the edge of the valve head is less than $\frac{1}{32}$" thick after grinding, replace the valve.

Reface valves to 45 degrees and true up seats to 46 degrees. Cutting a valve seat results in lowering valve spring pressure and increases the width of the seat. The nominal width of a valve seat is 1/16" to 3/32".

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

If a dial gauge is used to check the concentricity of valve seats, Fig. 11, the concentricity should be held to within .002".

HYDRAULIC VALVE LIFTERS

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose approximately 4 feet in length. Place the end of the hose near the end of each intake and exhaust valve with the other end of the hose near the ear. In this manner, the sound is localized, making it easy to determine which lifter is at fault.

Another method is to place a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish, carbon, etc. is found to exist in one unit, it more than likely exists in all the units.

Plungers are not interchangeable as they are selectively fitted at the factory. Should a plunger or lifter body become damaged, it is necessary to replace the entire unit, Fig. 12.

The plunger must be free in the lifter body. A simple test for this is to be sure the plunger will drop of its own weight in the body. There must be no excessive leakdown and there must be no ball check valve leakage.

Removal

Remove rocker arm covers and intake manifold. Back off rocker arm stud nuts until arms may be pivoted away from push rods. Lift out push rods and valve lifters.

Valve lifters should be placed in a rack in their proper sequence so they can be installed in the original locations in the block.

Disassemble & Assemble

1. Hold plunger down with push rod and, using a small screw driver or awl, remove plunger retainer.
2. Remove parts from lifter body.
3. Clean all parts and inspect for damage. If any parts are damaged, the entire lifter assembly should be replaced. The inertia valve in the plunger for rocker arm lubrication should move when the plunger is shaken.
4. To reassemble, invert plunger and set ball into hole in plunger. Place ball check valve retainer over ball and on plunger. Place check valve retainer spring over retainer. Assemble body over plunger assembly. Turn assembly over and install push rod seat. Compress plunger with push rod and install retainer.
5. Compress plunger to open oil holes and fill plunger with SAE 10 oil. Work plunger up and down and refill.

Fig. 12 Hydraulic valve lifter

Fig. 13 Timing gear oil nozzle removal. Chevy II

Installation

Reverse the order of the removal procedure to install the lifters and adjust the valve clearance as outlined previously.

TIMING CASE COVER

Chevy II

1. To remove cover, remove radiator.
2. Remove vibration damper (6-cyl.) or pulley (4-cyl.).
3. Remove oil pan.
4. Unfasten and remove cover.
5. Pry oil seal out of cover with a large screwdriver. Install new seal with open side of seal inside of cover and drive or press seal into place.
6. If oil nozzle is to be replaced, remove it with pliers as shown in Fig. 13. Drive new nozzle in place, using a suitable light plastic or rubber hammer.

Cover, Install

1. Clean gasket surfaces.
2. Install a suitable centering tool over end of crankshaft.
3. Coat gasket with light grease and stick it in position on block.
4. Install cover over centering tool, Fig. 14, and install cover screws, tightening them to 6 to 8 ft. lbs. *It is important that the centering tool be used to align the cover so the vibration damper installation will not damage the seal and position seal evenly around damper hub surface.*

V8 Engines

Remove vibration damper, oil pan, heater hose from water pump, and water pump from cylinder block. Unfasten and remove cover and gaskets.

Oil Seal

Pry old seal out of cover from the front with a large screwdriver. Install the new seal so the open end of the seal is toward the inside of the cover and drive it into position with a suitable driver, being sure to support cover at sealing area.

Fig. 14 Installing timing case cover. Chevy II

Fig. 16 Checking camshaft end play which should be .001 to .005". Chevy II and Chevrolet six cylinder

Fig. 17 Punch marks on timing gears are meshed for correct valve timing. Chevy II and Chevrolet six cylinder

Installation

1. Make certain that the mating faces of cover and block are clean and flat.
2. Make certain oil slinger is in place against crankshaft sprocket.
3. Coat oil seal with light grease and, using a new cover gasket, install cover and gasket over dowel pins in cylinder block.
4. Install and tighten cover screws to 6-8 lb. ft. torque.
5. Install oil pan, harmonic balancer and water pump.
6. Start engine and check for leaks.

Chevrolet 6

To remove the cover, remove oil cooler lines (if used), radiator, fan belt, vibration damper and oil pan. Remove timing case cover screws *and the two bolts that are installed from the back through the front main bearing cap.* Then remove the cover.

Before installing the timing gear cover, be sure that the oil seal is seated properly in its recess in the cover, otherwise premature wear of the seal will result, causing an oil leak.

When replacing the cover, use a sleeve which is the same size as the hub of the vibration damper, slipping it over the front end of the crankshaft to act as a guide when replacing the cover.

Apply a light film of grease on the inner circumference of the seal to prevent it from being damaged when the vibration damper is being installed.

Fig. 18 Checking timing gear backlash with feeler gauge. Lash should be .004 to .006". Chevy II and Chevrolet six cylinder

Fig. 15 Removing camshaft gear from camshaft. Chevy II and Chevrolet six cylinder

TIMING GEARS

Chevy II & Chevrolet 6

When necessary to install a new camshaft gear, the camshaft will have to be removed as the gear is a pressed fit on the shaft. The camshaft is held in position by a thrust plate which is fastened to the crankcase by two capscrews which are accessible through two holes in the gear web.

Use an arbor press to remove the gear and when doing so, a suitable sleeve, Fig. 15, should be employed to support the gear properly on its steel hub.

Before installing a new gear, assemble a new thrust plate on the shaft and press the gear on just far enough so that the thrust plate has practically no clearance, yet is free to turn. The correct clearance is from .001" to .005", Fig. 16.

The crankshaft gear can be removed by utilizing the two tapped holes in conjunction with a gear puller.

When the timing gears are installed, be sure the punch-marks on both gears are in mesh, Fig. 17. Backlash between the gears should be from .004" to .006", Fig. 18. Check the run-out of the gears, and if the camshaft gear run-out exceeds .004" or the crank gear run-out is in excess of .003", remove the gear (or gears) and examine for burrs, dirt or some other fault which may cause the run-out. If these conditions are not the cause, replace the gear (or gears).

Fig. 19 Timing marks aligned for correct valve timing. V8 engines

TIMING CHAIN

V8 Engines

1. Remove timing chain cover as outlined previously.

Fig. 20 Checking timing gear alignment. All sixes

2. Remove crankshaft oil slinger.
3. Crank engine until "O" marks on sprockets are in alignment, Fig. 19.
4. Remove three camshaft-to-sprocket bolts.
5. Remove camshaft sprocket and timing chain together. Sprocket is a light press fit on camshaft for approximately ⅛". If sprocket does not come off easily, a light blow with a plastic hammer on the lower edge of the sprocket should dislodge it.
6. If crankshaft sprocket is to be replaced, remove it with a suitable gear puller. Install new sprocket, aligning key and keyway.
7. Install chain on camshaft sprocket. Hold sprocket vertical with chain hanging below and shift around to align the "O" marks on sprockets.
8. Align dowel in camshaft with dowel hole in sprocket and install sprocket on camshaft. *Do not attempt to drive sprocket on camshaft as welch plug at rear of engine can be dislodged.*
9. Draw sprocket onto camshaft, using the three mounting bolts. Tighten to 15-20 lb. ft. torque.
10. Lubricate timing chain and install cover.

CRANKCASE FRONT END PLATE

Chevrolet 6

This plate is assembled to the cylinder block with from one to three gaskets which are used for the purpose of aligning the timing gears. To check the alignment of the gears, install the front end plate to the block and use two gaskets, holding them in position with three screws. Then use a new (spare) camshaft thrust plate over the camshaft hole in the end plate and place a steel straight edge, Fig. 20, against the camshaft thrust plate and over the shoulder of the crankshaft to see whether these two surfaces are flush. If the scale strikes the shoulder on the crankshaft, add another gasket. On the other hand, if there is space between the scale and the crankshaft shoulder, remove a gasket. When the desired result is obtained, assemble the screws and bolts, using a center punch to lock the screws.

CAMSHAFT

Chevy II

To remove the camshaft, remove radiator, grille, push rods, valve lifters, oil pan, vibration damper (6 cyl) or pulley (4 cyl), and timing case cover. Then pull out camshaft and gear assembly.

If necessary to replace bearings, the engine will have to be removed from the chassis. Then remove camshaft, flywheel and crankshaft. Drive out the expansion plug at the rear of the rear camshaft bearing and use suitable equipment to remove and replace the bearings.

V8 Engines

To remove the camshaft, remove valve lifters, fuel pump and its push rod, radiator, timing chain and camshaft sprocket. Install two $\frac{5}{16}$"-18 x 4" bolts in two camshaft bolt holes. Using these bolts as a puller, remove camshaft from engine.

Chevrolet 6

Camshaft end play should be from a free fit to a maximum of .003" and is controlled by a thrust plate at the front end of the shaft. This clearance can be checked by inserting a feeler ribbon between the front end of the shaft and the thrust plate, Fig. 16.

If necessary to replace bearings, drive out the expansion plug at the rear of the rear bearing and use suitable equipment to remove and replace the bearings.

Caution—Be sure the oil holes in the bearings are lined up with the oil holes in the crankcase. Before reaming the bearings, insert a round-nosed punch, Fig. 21, through the oil passage from the main to the camshaft bearings and stake each bearing in place.

Fig. 21 Using round-nosed punch to stake camshaft bearings in place. All sixes

Fig. 22 Correct assembly of rod to piston. V8 Engines. On Super Turbo-Thrust 348 engine, notch in piston head for cylinders 2-4-6-8 toward rear of engine (see Fig. 23)

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

Chevy II

Position the connecting rod in its respective piston so that the flange or heavy side of the rod at the bearing end will be toward the front of the piston (cast depression in top of piston head). Of course, when installed in the cylinder, the cast impression in the piston head will face the front of the engine.

V8 Engines

All pistons have an "F" cast on the front side. There is also a notch cast in the top of the piston head at the front to facilitate proper installation. The piston assemblies should always be installed with the notch toward the front of the engine, Fig. 22.

The odd numbered piston assemblies will always be installed in the left bank of cylinders, while the even numbered piston assemblies will always be installed

Fig. 23 Piston installation in high performance V8-348 engine

in the right bank of cylinders.

The heavy side of the bearing end of the rod goes to the rear of the engine on the right bank. On the left bank, the heavy side of the bearing end of the rod goes to the front of the engine.

Service Note, V8-348

When installing pistons in V8-348 engines with special camshaft (compression ratio of 11 and 11.25 to 1) be sure that they are installed as shown in Fig. 23.

Chevrolet 6

The connecting rod should be assembled to the piston so that when placed in the cylinder bore, the piston pin clamp bolt faces the camshaft side of the engine.

PISTONS

A .001″ oversize piston is available for service use so that proper clearances can be obtained for slightly worn cylinder bores requiring only light honing to clean up the bores. In addition, oversizes of .020″, .030″ and .040″ are available. If the cylinders have less than .005″ taper or wear they can be reconditioned with a hone and fitted with the .001″ oversize piston.

PISTON PINS

Chevy II

Piston pins are a matched fit to the piston and are not available from Chevrolet separately. Piston pins will not become loose enough to cause a knock or tapping until after very high mileage. In such cases, a new piston and pin assembly should be installed.

Piston pins should be capable of supporting their own weight in either pin boss when coated with light engine oil and at 60°F. Higher or lower temperatures will cause false indications.

V8 Engines

Piston pins are mounted off center and are a tight press fit in the connecting rods and pivot in the pistons. Pins should be capable of supporting their own weight in either pin boss when coated with light engine oil at 60°F. temperature. Higher or lower temperatures will cause false indications. Pistons and pins are supplied as an assembly.

Chevrolet 6

Pistons used in these engines are aluminum and not fitted with bushings.

To remove a piston pin, remove the piston pin clamp bolt and expand the clamp slot with a screwdriver or other suitable means. Then push the pin out of the piston with hand pressure. If it cannot be removed with hand pressure, use a suitable drift to drive it out.

When removing a pin with a drift, hold the piston in one hand, insert the drift and tap lightly with a hammer. Do not hold the connecting rod during this operation, otherwise misalignment of the rod may occur.

If the new pin cannot be installed in the piston with thumb pressure, enlarge the holes with an expansion reamer. Take only a light cut with the reamer. Ream the holes until the pin can be pushed into the piston with the pressure of both thumbs.

PISTON RINGS

When new rings are to be installed without reboring cylinders, the glazed cylinder wall should be slightly dulled but without increasing the diameter of the bore. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches down into the bore to which it is being fitted. An inverted piston can be used to push the rings down to this position. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If the feeler gauge is inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance may result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

Fig. 24 Checking crankshaft bearing clearance with Plastigage

ROD BEARINGS

Connecting rod bearing inserts are available in standard size and undersizes of .002″, .010″, .020″ and .030″. The bearings can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves of the bearing. The clearance between the bearing and crankshaft can be measured by the use of Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall the cap and tighten to the torque value given in the *Engine Tightening* chart.
4. Remove bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage scale, Fig. 24. The number within the graduation on the envelope indicates the clearance in thousands of an inch. If this clearance is greater than .004″ on an old bearing or greater than .003″ on a new bearing, or less than .001″, replace the bearing.

MAIN BEARINGS

1955-62 (Except '55 Six)

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out, Fig. 25.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening* table.

Fig. 25 Special plug for removing and installing upper main bearing halves

1955 Six

To install new main bearings, proceed as follows:

1. Remove radiator, vibration damper, fan belt, and spark plugs.
2. Loosen all rocker arm screws to relieve tension on camshaft.
3. Raise front and rear of car about 8" off floor, keeping car level.
4. Remove transmission floor pan and flywheel underpan.
5. Unfasten transmission support from cross member.
6. Uncouple gearshift selector rod from selector lever.
7. Raise rear of engine and support it with a bar across frame braces.
8. Release clutch fork from ball.
9. Unfasten transmission and slide it back about ¾".
10. Remove oil pan and timing cover.
11. Remove oil pump and screen.
12. Rotate crankshaft to best possible position for removal of all bearing caps and mark timing gear position to allow for reassembly in same position.
13. Loosen all main bearing cap bolts, allowing crankshaft to drop about ⅜".
14. Remove No. 2 and 4 bearing caps and take out upper and lower shells.
15. Install new upper bearing shells, locating dowel in hole and pressing bearings in place. If bearing has correct spread, shells should snap into place.

CRANKSHAFT REAR OIL SEAL

Chevy II

Both halves of the seal, Fig. 26 can be removed without removal of the crankshaft. Always replace upper and lower seal as a unit.

1. Remove oil pan and rear main bearing cap.
2. Remove seal from groove, prying from bottom with a small screwdriver.
3. Clean crankshaft surface. Then insert a new seal, well lubricated with engine oil, in bearing cap groove. *Keep oil off parting line surface as this surface is treated with glue.*
4. Gradually push with a hammer handle until seal is rolled into place.
5. To replace upper half of seal, use a small hammer and brass pin punch to tap one end of seal until it protrudes far enough to be removed with pliers. Install the new seal.
6. Install bearing cap and oil pan.

1955-58 V8's and 1959-62 Six

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade, Fig. 27.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

1959-62 V8 Rubber Seal

When necessary to correct an oil leak due to a defective seal, always replace the upper and lower seal halves as a unit. *When installing either half, lubricate the lip portion only with engine oil, keeping oil off the parting line surface as this is treated with glue.* Always clean crankshaft surface before installing a new seal. Be careful of seal retainer tang while inserting a new seal so that it doesn't cut the seal.

1. To replace the lower seal, remove seal from groove in bearing cap, using a small screwdriver to pry it out.
2. Insert new seal and roll it in place with finger and thumb.
3. To replace the upper seal (with engine in car) use a small hammer and tap a brass pin punch on one end of the seal until it protrudes far enough to be removed with pliers.
4. Insert the new seal, gradually pushing with a hammer handle until seal is rolled into place.
5. Install bearing cap with new seal and tighten bearing cap bolts.

Fig. 26 Crankshaft rear oil seal. Chevy II

Fig. 27 Installing oil seal in bearing cap. V8 Engines

OIL PAN

Chevy II

1. Disconnect battery ground strap.
2. Remove starter.
3. Disconnect steering idler arm bracket at right frame side rail and swing steering linkage down for pan clearance.
4. On 6 cylinder only, remove front crossmember. On station wagon, let stabilizer bar hang while removing crossmember.
5. Unfasten and remove pan.

Installation

1. Install seal in rear main bearing cap. Install front seal in timing gear cover, pressing tips into holes provided in cover.
2. Install side gaskets in cylinder block, using grease as a retainer. Side gasket tabs index into notches of front seal.
3. Install oil pan. *Screws into timing gear cover should be installed last. They are installed at an angle and*

holes line up after rest of pan bolts are snugged up.

1959-62 V8

1. Drain crankcase and cooling system.
2. Disconnect hoses at radiator.
3. Disconnect ground strap at engine.
4. If equipped with synchromesh transmission, disconnect clutch pedal push rod at clutch pedal control, intermediate lever and shaft. Remove clutch pedal control, intermediate lever and shaft assembly at frame mounting bracket, leaving shaft assembly attached to engine.
5. Remove fuel pump.
6. If equipped with Air Suspension, disconnect hose to alcohol vaporizer bottle and hose assembly from air compressor to accumulator tank.
7. Remove accelerator control rod from its lever.
8. If equipped with power brake, remove vacuum hose at check valve at engine manifold.
9. If equipped with power steering, remove power pump from generator in order to clear power brake master cylinder.
10. Remove transmission lower control rods at transmission levers.
11. Disconnect and lower exhaust pipe and muffler assembly from exhaust manifold.
12. Remove oil filter.
13. Loosen transmission mounting bolts.
14. Remove long bolt from each front mounting.
15. Turn crankshaft so that vibration damper keyway slot is at bottom of engine. This will position crankshaft counterweights so baffle in oil pan will clear.
16. Engine will have to be raised approximately 3″ to clear frame crossmember for oil pan removal. Raise engine until transmission housing comes in contact with underbody toe pan. Note clearance at fan blade and shroud while lifting engine and adjust for clearance as required.
17. Remove pan bolts and tilt oil pan while removing.

Note—Removal of the oil pan with Turboglide transmission installed is identical to the foregoing procedure except that the transmission control lever cross shaft at the transmission shifter lever and shaft assembly must be removed.

1958 V8

1. Remove distributor cap to prevent damage to it when engine is jacked up.
2. Remove exhaust crossover pipe and manifold heat valve.
3. Remove front engine mounting bolt nuts.
4. Turn crankshaft so that vibration damper keyway slot is at bottom of engine. This will index crankshaft counterweights so baffle in oil pan will clear.
5. Raise engine from below at vibration damper. Engine will have to be raised about three inches to clear frame cross member for oil pan removal. Note clearance at fan and shroud while lifting engine and adjust for clearance as required.
6. Unfasten and remove oil pan.
7. Reverse above procedure to install pan and tighten attaching bolts to a torque of 12-15 lb. ft.

1955-57 V8

To remove the oil pan, drain the oil and disconnect steering idler arm bracket from frame side rail and drop for clearance. Unfasten and remove oil pan.

After the pan is installed, tighten $\frac{5}{16}$″ bolts to a torque of 12-15 lb. ft. and ¼″ bolts to 6-9 lb. ft.

1955-57 Six

To remove the oil pan, drain the oil. Disconnect the steering idler arm bracket from the right hand frame side rail and drop for clearance. Unfasten oil pan from crankcase and remove pan. *Crankshaft may have to be turned to allow clearance at front cross member.*

1958 Six

1. Scribe alignment marks on hood around hood hinges; then remove hood.
2. Remove battery ground cable.
3. Disconnect fuel pipe at pump.
4. Remove generator lead wires and loosen fan belt.
5. Remove radiator.
6. Disconnect transmission oil cooler lines on Powerglide models.
7. Remove fan and pulley.
8. Remove rocker arm cover and attach a suitable lifting rig to engine. Using a chain hoist or equivalent, lift engine only enough so that engine will be supported when front engine mounts are removed.
9. Remove center bolts from each front mount.
10. On synchromesh transmission models, disconnect clutch idler shaft bracket from engine; remove overdrive solenoid (if equipped); remove flywheel underpan extension; disconnect shifter rods at transmission.
11. On automatic transmission models, disconnect transmission oil cooler lines, and transmission control linkage at transmission.
12. Disconnect propeller shaft from rear axle, remove center mount support bolts and slide to rear until free of transmission.
13. Drain transmission and remove transmission cross member and mounting block.
14. Disconnect speedometer cable at transmission.
15. Drain crankcase oil and remove oil pan bolts.
16. Raise engine high enough so that oil pan clears cross member and pan can be removed through front of engine compartment. Crankshaft may have to be rotated to allow oil pan to clear counterweights.

1959-61 Six

1. Drain crankcase and radiator.
2. Disconnect hoses at radiator.
3. Disconnect ground strap at engine.
4. Disconnect gas tank feed pipe at fuel pump.
5. Disconnect accelerator control rod at its lever.
6. If equipped, remove overdrive solenoid.
7. Disconnect power brake hose at check valve.
8. Remove oil filter and support bracket assembly to clear power brake master cylinder.
9. Disconnect exhaust pipe from manifold.
10. Disconnect transmission lower control rods at transmission.
11. Disconnect clutch fork push rod at fork.
12. Disconnect clutch pedal control, intermediate lever and shaft from engine.
13. Loosen transmission mounting bolts and remove front engine mounting bolts.
14. Remove hood and lift engine approximately 3″ until valve rocker cover comes in contact with dash upper panel.
15. Remove bolts and oil pan. If equipped with synchromesh transmission, remove flywheel under pan extension before removing oil pan. Crankshaft may have to be turned to clear counterweights.

1962 Chevrolet Six Std. Trans.

Removal of the oil pan from these engines is accomplished in the same manner as described for 1961 models.

1962 Chevrolet Six With P.G.

If the oil pan has to be removed for a bearing job, the engine will have to be removed from the chassis. However, when a job requires oil pan removal and cylinder head removal as for a ring job, the pan can be removed as outlined for 1961 models after the head has been removed. It may be necessary to rotate the crankshaft to position the front crank throw and counterweights crossways to the engine for pan removal clearance.

Oil pan gaskets and seals or the rear main bearing oil seal can be replaced without the complete removal of the pan from the vehicle as follows:

1. Remove rocker arm cover.
2. Disconnect exhaust pipe at manifold and transmission shifter bellcrank at transmission.
3. Loosen engine rear mount and remove through-bolts at engine front mounts.
4. Raise front of engine with a jack under oil pan or vibration damper high enough to place a 2-inch spacer block under each engine front mount. *While raising engine, carefully observe fan and radiator hose clearances.*
5. Place blocks under front mounts and remove jack.
6. Unfasten and lower oil pan to frame.
7. Move oil pan forward between sway bar and vibration damper to gain 4 to 6 inches of clearance for rear main bearing oil seal replacement.
8. To replace pan gaskets and seals, the pan can be manipulated to gain access to each piece and to wipe the pan clean. There is adequate clearance to scrape gasket surfaces if necessary.

OIL PUMP

Chevy II

The pumps used in these engines are of the positive gear type. After disassembling the pump, examine the shaft and gears for excessive wear and replace where necessary, or better still, install a new pump. When assembling the pump, be sure the ground side of the idler gear is toward the cover.

The gasket used between the pump cover and the body is special in that it controls the clearance in the pump. If the relief valve parts show wear, install new parts. Be sure that the tapered set screw which holds the pump in place is fully seated and locked with its lock nut.

V8 Engines

After removing the oil pan, unfasten pump from rear main bearing cap. Disconnect pump shaft from extension by removing clip from collar. Remove pump cover and take out idler gear, drive gear and shaft.

Should any of the following conditions be found it is advisable to replace the pump assembly.

1. Inspect pump body for cracks or wear.
2. Inspect gears for wear or damage.
3. Check shaft for looseness in housing.
4. Check inside of cover for wear that would permit oil to leak past the ends of gear.
5. Check oil pick-up screen for damage to screen, by-pass valve or body.
6. Check for oil in air chamber.

Chevrolet 6

The pumps used in these engines are of the positive gear type. After disassembling the pump, examine the shaft and gears for excessive wear and replace where necessary, or better still, install a new pump. When assembling the pump, be sure the ground side of the idler gear is toward the cover.

Note—The gasket which is used between the pump cover and the body is special in that it controls the clearance in the pump. If the relief valve parts show wear, install new parts. Be sure that the tapered set screw which holds the pump in place is fully seated and locked with its lock nut.

RADIATOR

Chevy II

The radiator is fastened in place with six attaching bolts (3 each side). Remove these bolts and lift radiator out of vehicle.

Chevrolet

1. To remove the radiator, drain radiator and remove radiator-to-water outlet hose.
2. Remove radiator-to-inlet pipe hose.
3. On Powerglide or Turboglide models, remove oil cooler lines from radiator and plug lines and radiator fittings.
4. Unfasten radiator from its support and lift out.

Fig. 28 V8 water pump

WATER PUMP

Chevy II

1. After unfastening the pump, pull it straight out of the cylinder block to avoid damage to the impeller and shaft.
2. When disassembling the pump, support the fan hub in an arbor press and press pump shaft out of hub. A ½″ x 2″ bar will allow the shaft to be pushed through the hub.
3. Support pump in arbor press and press shaft and impeller out of pump, applying pressure on outer race of bearing only. *Shaft and bearing must not be pushed out of housing by applying force on shaft or bearings will be damaged. Use a ⅞″ deep socket or piece of tubing 1⅛″ O.D.* Shaft and bearing should be pressed out of rear of pump body only.
4. Support impeller on seal surface. Using a ½″ x 2″ pin, press shaft out of impeller. Discard seal.
5. When assembling pump, apply pressure to outer race of shaft bearing until it is flush with front of pump body.
6. Lightly coat O.D. of new seal with sealing compound and press into place, applying pressure to seal outer flange. Seal should bottom with outer flange against pump body.
7. Press on fan hub, being sure it is positioned so that fan belt operation will not be hampered.
8. Impeller should be pressed on shaft so there is .010″ to .035″ clearance between impeller vanes and pump body.

Chevrolet

1. Drain radiator and remove water inlet hose from pump.
   Remove fan belt.
   On heater equipped models, remove hose from pump housing.
   Unfasten pump from engine and lift off.
5. Remove fan and pulley.
6. Remove pump back plate.
7. Support fan hub on arbor press and press pump shaft out of hub.
8. Support pump on cylinder block face and press shaft and impeller out of pump, applying pressure on outer race of shaft bearing only. Shaft and bearing assembly must not be pushed out of housing by applying force on shaft or bearings will be damaged. Use a ⅞″ deep socket or a piece of tubing 1⅛″ O. D.
9. Press shaft out of impeller. Discard seal.

Assembly & Installation

Inspect all parts for wear or damage. Do not submerge shaft bearing in cleaning solvent as it is permanently sealed and lubricated.

Assemble pump in reverse order of disassembly. When installing the seal see that it bottoms with the outer flange against the pump body. The impeller should be pressed on the shaft so that there is .010″ to .035″ clearance between impeller vanes and pump body. See Fig. 28 for position of shaft, fan hub and impeller in pump housing.

DISTRIBUTOR

Removal

1. Disconnect distributor primary wire from coil terminal.
2. Remove distributor cap and rotor. *Mark position of rotor arm on dis-*

Fig. 29 Ignition details. 1955-56 V8

Fig. 30 Ignition details. [illegible], 283, 327

Fig. 31 Ignition details. V8-348 and V8-409

tributor housing so distributor can be installed in same position.

3. Remove vacuum line from distributor.
4. Remove distributor hold-down clamp.
5. Note relative position of distributor in block, then work it out of the engine.

Installation

1. Turn rotor about ⅛ of a turn counterclockwise past the mark previously placed on the distributor housing.
2. Push the distributor down into the block with the housing in the normal "installed" position. *It may be necessary to move the rotor slightly to start gear into mesh with camshaft gear, but rotor should line up with mark when distributor is down in place.*
3. Tighten distributor clamp screw snugly and connect vacuum line, primary wire to coil, and install cap. If spark plug wires were removed from cap, refer to Figs. 29, 30, 31.

Service Note

If the engine was disturbed while the distributor was removed from the engine, first crank the engine to bring No. 1 piston up on its compression stroke and continue cranking until the timing mark is adjacent to the timing indicator. Then rotate the distributor cam until the rotor is in position to fire No. 1 cylinder. Install the distributor as outlined above and set the ignition timing as directed below.

IGNITION TIMING

Chevy II

When setting ignition timing, it is essential to interpret correctly the graduations of the timing tab attached to the engine front cover, Figs. 32 and 33. The markings on this tab are in two degree increments from the "O" mark. All timing tabs used are designed with the greatest number of graduations appearing on the advance ("A") side of the "O" marking. It is on this side of the timing tab "O" marking that all BTDC settings will fall. The "O" mark is TDC.

When using a timing light to set ignition timing, disconnect the spark advance vacuum hose from the distributor vacuum advance unit. With vacuum hose removed, cover it with a piece of tape. For correct timing, see *Tune Up* chart.

1958-62 V8 Service Note

During mid-season of 1958 and thereafter the distributor vacuum advance tube is connected directly to the intake manifold instead of to the carburetor throttle body. This vacuum advance tube must be disconnected when setting ignition timing as full advance is present at idle speed. Do not forget to reconnect the tube after timing has been set.

To adjust the timing, crank the engine to bring No. 1 piston up on its compression stroke and stop when the mark on the harmonic balancer lines up with the proper mark on the timing tab attached to the chain cover. Loosen the distributor clamp and rotate the distributor until the points just break. Tighten the distributor clamp.

When a timing light is used the engine should be run at hot idling speed for if it is turning faster the spark may be advanced by the centrifugal weights in the distributor and the timing will not be correct.

Chevrolet 6

Set the octane selector at zero. Check to see that the vacuum control operates freely, and is in full retard position. Crank the engine until No. 1 piston is coming up on its compression stroke and the steel ball in the flywheel registers with the line on the inspection hole in the flywheel housing. Loosen the distributor clamp screw and turn the housing until the points just break. Then set the octane selector so that a slight ping is heard on open throttle at 10 to 15 MPH.

When a Neon timing light is used, the engine should be run at idling speed for if it is turning faster the spark may be advanced by the centrifugal weights on the distributor and the timing will not be correct. The stroboscopic effect of the Neon light makes the ball appear to stand still in relation to the pointer at the flywheel opening. The distributor can then be rotated until the ball appears to remain exactly in line with the pointer, when the timing is correct. The factory recommends using the Neon light in timing the ignition.

STARTER, REPLACE

Chevy II

1. Disconnect lead wires from S, R, and battery terminals. Observe and record color coding of lead wires to insure proper reinstallation.
2. Remove starter pad mounting bolts. Remove stud nut at front of motor and rotate bracket out of the way.
3. Pull starter forward to clear housing and remove from engine.

Fig. 32 Ignition timing marks (2 degree increments.) Chevy II six cylinder

Fig. 33 Ignition timing marks (2 degree increments). Chevy II four cylinder

1959-62 Chevrolet

1. Disconnect battery ground strap and remove cable from fender clip.
2. Unplug starter motor harness dash connector.
3. Unfasten starter from its mounting.
4. Pull starter forward to clear housing and carefully lower it.

1955-58

Disconnect ground strap from battery and cable and wires from starter solenoid. Unfasten and remove starter from clutch housing.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Cut-Out On Turns

1960 Rochester 4GC-7013004, 7013006, 7013010, 7013012—Recent changes in the design of these carburetors make new float settings necessary. These changes are the addition of a torsion spring on a new design float hanger. The torsion spring will eliminate engine cut-out that was sometimes experienced while hard cornering a vehicle with fully warmed engine. Passenger cars effected by these changes are those equipped with 283 or 348 engines with automatic transmission in combination with air-conditioning.

A change has also been made for non-air conditioned cars with automatic transmission. In these carburetors only the float hanger has been redesigned. Carburetors with this change can be identified by a tag with the letter "B" stamped on it.

These carburetors can be modified to incorporate new float hangers and torsion springs by installing Kit No. 7017-804. which includes two new floats, two torsion springs, two fibre float gauges and one each of tags stamped 7015004, 7015006, 7015010 and 7015012.

Modification of carburetors 7013004 and 7013006 (with letter "B") to incorporate the torsion springs can be made by using Kit No. 7017803, which contains two torsion springs and one each of tags stamped 7015004 and 701-5006.

Acceleration Stumble During Engine Warm-up

1959-60 V8 With 2GC Units—To correct this condition a new pump modification kit (part No. 7019742) has been released. The kit includes a new pump assembly, pump return spring and a brass identification tag, code stamped "D". The duration spring on the new pump assembly and pump return spring has more tension and both springs must be installed together for best operation.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

CARTER NOTES

METERING ROD

WCFB and WGD—This adjustment must be made after pump setting. Back out throttle set screw until throttle valves are fully closed and loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip on vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—WCFB float level. Adjust by bending float arms.

Fig. ②—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ③—With pump connector link in outer hole of pump arm, flat on pump arm should be parallel with a straightedge placed on dust cover boss. Adjust by bending throttle connector rod.

④—With engine at normal operating temperature, rotate fast idle cam so fast idle screw rests on high step or index mark of cam. Adjust fast idle screw to obtain specified rpm.

⑤—With throttle wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending lip on throttle shaft lever.

⑥—Position fast idle screw on high step of fast idle cam. Adjust dashpot plunger screw so it will just contact throttle lever. Check dashpot action (engine running at hot idle speed) by snapping throttle open and shut. If engine races, turn plunger screw ½ turn clockwise; if engine stalls, turn screw ½ turn counter-clockwise.

Fig. ⑦—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑧—WGD float level. Adjust by bending float lever.

CARTER NOTES

continued

⑨—Turboglide models only. With throttle valves fully closed, adjust dashpot position so that with plunger fully depressed, there should be the clearance specified between plunger and contact arm. With engine idling, test dashpot action by snapping throttle open and shut. If engine races increase clearance; if engine stalls reduce clearance.

Fig. ⑪—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ⑬—Measured between upper edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle lever.

Fig. ⑩—AFB float level. Adjust by bending float lever.

Fig. ⑫—Measured from top of bowl cover to top of plunger shaft. Adjust by bending throttle connector rod.

ROCHESTER NOTES

Fig. ①—4GC float level.

Fig. ②—4GC float drop.

Fig. ③—With throttle valves closed, measure from top of air horn casting to bottom of pump plunger shaft. Adjust by bending pump rod.

Fig. ④—Bend unloader tang on fast idle cam to obtain clearance specified between choke valve edge and dividing wall of air horn with throttle valves wide open.

Fig. ⑤—2GC float level.

Fig. ⑥—2GC float drop.

Fig. ⑦—With throttle valves fully closed, bend pump rod as necessary to obtain measurement specified from top of pump housing to top of pump rod.

Fig. ⑧—With throttle valves wide open, choke valve must be open to the clearance specified between edge of choke valve and inner wall of air horn. Adjust by bending tang on throttle lever.

Fig. ⑨—BC float level.

(Continued next page)

Fig. ⑩—BC float drop.

⑪—Position fast idle screw on high step of fast idle cam. Adjust dashpot plunger screw so it will just contact throttle lever. Check dashpot action (engine runnig at hot idle speed) by snapping throttle open and shut. If engine races, turn plunger screw ½ turn clockwise; if engine stalls turn screw ½ turn counter-clockwise.

ROCHESTER NOTES continued

⑫—Turboglide models only. With throttle valves fully closed, adjust dashpot position so that with plunger fully depressed, there should be the clearance specified between plunger and contact arm. With engine idling, test dashpot action by snapping throttle open and shut. If engine races increase clearance; if engine stalls reduce clearance.

⑬—For units with letter "B" stamped on number tag: Primary 1 33/64", secondary 1 37/64".

Fig. ⑭—Make pump adjustment before adjusting idle vent valve as shown.

Fig. ⑮—Make pump adjustment before adjusting idle vent valve as shown.

⑯—With end of fast idle screw on next to highest step on fast idle cam, see if a gauge of the thickness listed will slide easily between lower edge of choke valve and bore of carburetor. If necessary, bend choke rod as required.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1955-56

Loosen the lock nut on the clutch fork push rod and turn adjusting nut to remove all lash at the fork, then back off two turns. Tighten lock nut.

1957

Remove the cotter pin, washer and spring from the clutch fork push rod and turn the adjusting block until free pedal travel is ¾" to 1". (One turn equals about 3/16" at pedal.) Install spring, washer and cotter pin.

1958-61 With Dimple On Cross Shaft Lever

1. Disconnect forward end of clutch fork push rod from cross shaft lever.
2. Move fork push rod rearward to remove all lash. With the rod held in this position, adjust swivel on push rod so that the conical point of the swivel lines up with the "dimple" in the cross shaft lever.
3. Hold swivel position on rod and reconnect swivel to cross shaft lever.

Early 1961 With No Dimple

1. Disconnect swivel from cross shaft lever.
2. With push rod held all the way rearward, to eliminate lash between release bearing and clutch spring, check for free entry of swivel into cross shaft lever hole.
3. If swivel pin does not line up with hole, loosen jam nuts on both ends of swivel.
4. Adjust swivel to align with hole in cross shaft lever.
5. Adjust jam nuts finger tight next

Fig. 1 Clutch linkage adjustment. Chevy II

Fig. 2 Diaphragm spring type clutch

to swivel. Then hold rear nut and tighten front nut to a torque of 15-20 ft. lbs. to collapse the special washer.

6. Install clip into swivel. This adjustment will give ¾" to 1" free travel at the clutch pedal.

1962 Chevrolet

Adjustment is made on the lower end of the pedal push rod. Adjust the push rod to there is free pedal travel of ⅞" to 1⅛".

Chevy II

There is one linkage adjustment (clutch fork push rod) to compensate for all normal clutch wear.

The clutch pedal should have ¾" to 1" free travel (measured at clutch pedal pad) before the clutch release bearing engages the clutch diaphragm spring levers.

1. Referring to Fig. 1, loosen lock nut "A" and lengthen or shorten push rod in swivel as required by turning with wrench on machined flat "B". (Shorten push rod to increase pedal lash.)
2. Hold flat "B" and tighten lock nut "A". *A measurement of approximately ⅛" between push rod and its seat in fork will give required free pedal travel.*

CLUTCH, REPLACE

Chevy II

1. Remove transmission as outlined further on.
2. Disconnect clutch linkage return spring from clutch fork and let push rod hang free of fork.
3. Remove release bearing from fork.
4. Remove attaching screws and remove clutch housing.
5. Slide clutch fork from ball stud and remove fork from dust boot.
6. Loosen clutch attaching bolts a little at a time until clutch diaphragm spring tension is relieved. Then remove clutch.
7. Replace in the reverse order of removal and adjust clutch linkage.

Chevrolet & Corvette

1. Remove transmission.
2. Remove clutch release bearing from fork.
3. Remove clutch fork tension spring.
4. Disconnect clutch fork push rod.
5. To remove fork, force it forward and toward center of vehicle.
6. Loosen clutch attaching bolts one turn at a time until diaphragm spring tension is released. Then remove bolts and take clutch from vehicle.

CLUTCH SERVICE

Note—*Except for 1956-57 models with Power Package and 1958 with 348 cu. in. engine, all models with standard transmission are equipped with the diaphragm spring type clutch, Fig. 2. The 1958 348 cu. in. engine and 1956-57 Power Package include a conventional coil spring type clutch.*

While it is practical to overhaul the diaphragm spring type clutch, as given below, unless special clutch rebuilding equipment is available, it is recommended that the coil spring type clutch be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If special clutch rebuilding equipment is available, follow the equipment manufacturer's instructions.

Fig. 3 Clutch release bearing lubrication. All Models with diaphragm spring type clutch

Disassemble

1. Remove three drive strap-to-pressure plate bolts and retracting springs and remove pressure plate from clutch cover. *When disassembling, note position of grooves on edge of pressure plate and cover. These marks must be aligned at assembly to maintain balance.*
2. The diaphragm spring and two pivot rings are riveted to the clutch cover.

Fig. 4 Exploded view of 1955 synchromesh transmission

Fig. 5 Exploded view of 1965-62 three speed synchromesh transmission. Chevy II transmission uses only one thrust washer at each end of cluster gear

Spring, rings and cover should be inspected for excessive wear or damage and if there is a defect, it is necessary to replace the complete cover assembly.

Inspection

1. Wash all parts except the release bearing in cleaning solvent. *The release bearing is permanently packed with lubricant and should not be soaked in cleaning solvent as this may dissolve the lubricant.*
2. Inspect pressure plate and flywheel for scores on contact surfaces.
3. Check drive-straps for looseness at the clutch cover rivets and evidence of looseness at pressure plate bolt holes.
4. Check release bearing for roughness and free fit on sleeve of clutch shaft bearing retainer.
5. Inspect clutch disc for worn, loose or oil soaked facings, broken springs, loose rivets or riding.
6. Examine splines in hub and make sure they slide freely on splines of clutch shaft. If splines are worn, clutch disc or clutch shaft should be replaced as necessary.

Assemble

1. Install pressure plate in cover, lining up groove on edge of pressure plate with groove on edge of cover.
2. Install pressure plate retracting springs and drive strap-to-pressure plate bolts and lockwashers. Tighten to 11 lb. ft. torque. The clutch is now ready to be installed.

Installation

1. Hand crank engine until "X" mark on flywheel is at bottom.
2. Install clutch disc, pressure plate and cover assembly, and support them with clutch pilot tool or spare clutch shaft.
3. Turn clutch assembly until "X" mark on cover flange lines up with "X" mark on flywheel. Align nearest bolts holes in clutch and in flywheel.
4. Install attaching bolts and tighten each one a turn at a time to prevent distorting the cover as the spring pressure is taken up.
5. Remove clutch pilot tool.
6. Pack clutch fork ball seat with a small amount of high melting point grease.
7. Install fork on ball in clutch housing.
8. Lubricate recess on inside of release bearing collar and coat release fork groove with a small amount of graphite grease, Fig. 3.
9. Install release bearing assembly to the fork and hook up linkage.
10. Install transmission.

COIL SPRING TYPE

1958 V8-348

Remove transmission as outlined further on. Then, before removing clutch from flywheel, mark with a punch the flywheel, clutch cover and one pressure plate lug so that these parts may be

assembled in their same relative positions, as they were balanced as an assembly.

Disengage the clutch fork from the ball stud and remove the ball stud by screwing it rearward out of the clutch housing. Loosen the holding screws a turn or two at a time to avoid bending rim of cover. When removing clutch disc be sure to mark flywheel side. *It is advantageous to place nuts or metal spacers between the three clutch levers and the cover to hold the levers down as the holding screws are removed.*

Installation

Assemble clutch disc and clutch cover assembly to flywheel in accordance with marking on clutch disc for flywheel side. *Depress clutch levers and install spacers or nuts to hold levers down. This will facilitate installation and prevent cover distortion during tightening. Be sure to remove spacers before bolting clutch to flywheel.*

Line up the clutch disc and pilot bearing with a dummy shaft before tightening cover holding screws. Tighten holding screws before removing dummy shaft.

After transmission has been installed, adjust clutch pedal free play as directed above.

MANUAL SHIFT TRANSMISSION

Replace, Chevy II

1. Disconnect speedometer cable and shift control rods at transmission.
2. Remove propeller shaft.
3. Support rear of engine and remove transmission mounting block-to-support (crossmember) bolts. Remove support-to-frame bolts and support.
4. Remove two top transmission-to-clutch housing capscrews and insert guide pins in these holes.
5. Remove the two lower attaching capscrews and slide transmission back and out of car.
6. Reverse removal procedure to install the transmission.

Replace, 1955-57

1. Disconnect speedometer cable, and the shift control rods from the levers at the transmission.
2. Split the rear universal joint and remove the propeller shaft and front universal joint.
3. Remove the two top transmission-to-clutch attaching bolts and insert guide studs in their place.
4. Remove the two lower attaching bolts and slide the transmission straight back on the guide studs until the clutch gear is free of the splines in the clutch disc.
5. Remove the transmission from under the chassis.
6. Reverse the above procedure to install the transmission, using the guide studs to prevent the weight of the transmission from hanging on the clutch disc.

Replace, 1958-62 Chevrolet

1. Disconnect speedometer cable.
2. Disconnect shift control rods from shift levers at transmission.
3. Remove propeller shaft.
4. Support rear of engine and remove transmission mounting block-to-support bolts and washers.
5. Remove support from frame, noting number of shims present (if any) so the same amount may be installed.
6. Remove two top transmission attaching cap screws and insert guide pins in these holes. Remove two lower attaching screws.
7. Slide transmission straight back on the guide pins until the clutch gear is free of the clutch disc splines.
8. Remove transmission from under body.
9. Reverse above procedure to install the transmission.

Service Note

If high gear hop-out is experienced on Corvette V8-283 and Hi-performance 348 engines, it is probably due to the transmission-to-clutch housing bolts being too short.

To insure proper attachment of the manual transmission to the aluminum clutch housing on these engines, it is necessary that 1¾" bolts be used. It is possible for shorter bolts to loosen, resulting in transmission misalignment and high gear hop-out.

The 1¾" bolt specified for this usage is available under Part No. 427565. An installation torque of 40-50 ft. lbs. is recommended when these bolts are used in the aluminum housing.

THREE SPEED TRANSMISSION REPAIRS

Disassemble, 1955-62

1. Referring to Figs. 4 and 5, remove side cover.

Fig. 6 Removing main drive gear and bearing with puller. 1955.

2. Remove main drive gear bearing retainer and, with the puller shown in Fig. 6, remove the main drive gear and bearing.
3. Remove 24 roller rear pilot bearings, 2 washers and 14 roller front bearings.
4. Unfasten extension housing from transmission case and pull extension and mainshaft out of transmission case, leaving the synchronizer and first and reverse gear in case.
5. Remove synchronizer clutch sleeve and first and reverse gear through side opening in case.
6. Remove countershaft by driving it from front to rear of case, using a soft steel drift. Remove the countergear rollers and thrust washers (and thrust bearings on 1956-62).
7. Remove the countergear.
8. Drive the idler shaft lock pin into the shaft. This pin is shorter than the diameter of the shaft so the shaft may be slipped out when the pin is driven in.
9. Using a drift pin, tap rear of idler shaft to drive out plug ahead of shaft. Do not turn the shaft while removing as the lock pin may drop down between the idler gear bushings.
10. Remove reverse idler gear and thrust washers (and bearings on 1956-62).
11. To remove the mainshaft from the extension, expand the bearing snap ring and tap the rear of the shaft with a soft hammer to bring the shaft, speedometer drive gear, second speed gear and bearing out of the extension as an assembly.

Mainshaft, Disassemble

1. Press speedometer gear off mainshaft, using suitable split plates in an arbor press.
2. Remove bearing-to-mainshaft snap ring and press bearing off shaft.
3. Remove second speed gear thrust washer, pull drive pin out of shaft and remove second speed gear.

Mainshaft, Assemble

1. Slide second speed gear on mainshaft, insert drive pin in shaft and install thrust washer against gear.
2. Install new bearing with groove in outside diameter of bearing toward second speed gear.
3. Select one of four available snap rings so end play of bearing on shaft is a maximum of .004". This may be determined by installing successively larger rings. Use the thickest ring that will enter snap ring groove on shaft.
4. Start speedometer drive gear on shaft with chamfered inside diameter of gear toward bearing. Press gear on shaft so forward face of gear is ⅞" from rear face of bearing.

Transmission, Assemble

Reassemble the transmission in the reverse order of disassembly, observing the following details:

1. See that the synchronizer rings are smooth and that they do not rock in the cones. Excessive rocking affects proper synchronizing of gears during shifting.

2. When installing the reverse idler gear, the chamfered teeth should be placed to the rear of the case. Install the idler shaft, making sure that the lock pin hole in the shaft lines up with the hole in the case at the same angle, Fig. 7. It is well to line up these holes with a punch before installing the lock pin. Use a new lock pin and drive it in about $\frac{1}{16}$" beyond flush with the case, and peen the hole slightly.
3. When installing the countershaft the step on the forward end should be flush with the front face of the case, or about $\frac{1}{64}$" below the face to maintain proper transmission alignment.
4. When installing the mainshaft, the proper seating of the shoulder on the shaft against the inner race of the mainshaft rear bearing should permit .010" end play of the second speed gear.
5. When the assembly has been completed, check the transmission in all gears to be sure that there is no indication of binding in any position.

Fig. 7 Reverse idler gear, shaft and lock pin. All models

FOUR SPEED TRANS.

1960-62 Chevrolet

1. To disassemble, refer to Fig. 8 and remove side cover.
2. Remove front bearing retainer.
3. Drive lock pin from bottom side of reverse shifter lever boss and pull shifter out about ⅛". This disengages reverse shift fork from reverse gear.
4. Unfasten case extension from rear bearing retainer (5 bolts). Tap extension to rear. When reverse idler shaft is out as far as it will go, move extension to left so reverse fork clears reverse gear and remove extension.
5. Remove snap ring from end of mainshaft. Remove speedometer gear, reverse idler gear, tanged trust washer and reverse gear.
6. Remove self-locking bolt attaching rear bearing retainer to case. Then remove mainshaft assembly.
7. Lift front reverse idler gear and thrust washer from case.
8. Remove pilot rollers from main drive gear and 4th speed synchronizing ring.
9. Remove main drive gear snap ring and spacer washer. Tap drive gear from front bearing. From inside case, tap out front bearing and snap ring.
10. From front of case, tap out countershaft and remove countershaft gear and thrust washers.
11. Strip mainshaft of all parts.

Assemble Mainshaft

1. From rear of mainshaft, assemble 1st-2nd clutch to mainshaft with sleeve taper toward rear and hub to front. Press 1st gear bushing on shaft.
2. Install 1st gear synchronizing ring so notches in ring correspond to keys in hub.
3. Install 1st gear with hub to front, and thrust washer. Make sure that grooves in washer are facing 1st gear.
4. Press rear bearing with snap ring groove toward front, making certain bearing is firmly seated against shoulder on mainshaft.
5. Choose correct selective fit snap ring and install it in mainshaft groove behind rear bearing. Snap rings are available in three thicknesses; use ring that will produce from zero to .005" clearance between rear face of bearing and front face of snap ring.
6. From front of mainshaft, install 2nd gear synchronizing ring so notches in ring correspond to keys in hub. Install 2nd speed gear with hub toward rear, and install 2nd-3rd gear thrust (bearing) washer.
7. Install 3rd gear with hub to front and 3rd gear synchronizing ring with notches to front.
8. Install 3rd-4th gear clutch (hub and sliding sleeve) with taper toward front, making sure that keys in hub correspond to notches in 3rd gear synchronizing ring. Install snap ring in mainshaft groove in front of clutch.
9. Install rear bearing retainer plate. Spread snap ring on plate to allow it to drop around rear bearing and press on end of mainshaft until snap ring engages groove in rear bearing.
10. Install reverse gear with shift collar to rear.
11. Press speedometer gear on mainshaft so it is 4½" from center of gear to flat surface of rear bearing retainer. Install snap ring in groove at rear of mainshaft.

Assemble Countergear

1. Install spacer in countergear.
2. Using grease to retain rollers, install 20 rollers in each end of gear, two .050" spacers, 20 more rollers, then one .050" spacer. Insert dummy shaft to hold parts in place during installation.

Transmission, Assemble

1. Place countershaft tanged thrust washers in place, retaining them with grease and being sure that tangs are resting in notches in case. Set counter gear in bottom of case.
2. Press bearing onto main drive gear with snap ring groove to front and firmly seat bearing against shoulder of main drive gear.
3. Install spacer washer and selective fit snap ring in groove on gear stem. Use ring that will provide zero to .005" clearance between rear face of snap ring and front face of spacer washer.
4. Install main drive gear through side cover opening. Place snap ring in groove in front bearing.
5. With transmission resting on its front face, move countergear into mesh with main drive gear, being sure thrust washers are in place. Install key in end of countershaft and, from front of case, tap shaft until its end is flush with rear of case and dummy shaft is displaced. End play of countergear should be not more than .025".
6. Install 14 pilot rollers in main drive gear pocket, using grease to hold them in place.
7. Place a greased gasket on front face of rear bearing retainer.
8. Install 4th gear synchronizing ring on main drive gear with clutch key notches toward rear.
9. Position reverse idler gear thrust washer (untanged) on machined face of ear cast in case for reverse idler shaft. Position front reverse idler gear on top of thrust washer with hub facing rear of case.
10. Lower mainshaft assembly into case, making certain that notches on 4th gear synchronizing ring correspond to keys in clutch assembly.
11. Install self-locking bolt attaching rear bearing retainer to case, tightening it to 20-30 ft. lbs.
12. From rear of case, insert rear reverse idler gear, engaging splines with portion of gear within case.
13. Place greased gasket on rear face of rear bearing retainer.
14. Install remaining tanged thrust washer on reverse idler shaft, being sure tang is in notch in idler thrust face of extension case.
15. Place two clutches in neutral.
16. Pull reverse shifter shaft to left side of extension and rotate shaft to bring reverse shift fork to extreme forward position in extension. Line up forward and rear reverse idler gears, being sure front thrust washer is in place.
17. Start extension into transmission case by carefully inserting reverse idler shaft through reverse idler gears. Slowly push it on shifter shaft until shift fork engages reverse gear shift collar. When fork engages, rotate shifter shaft to move reverse gear rearward, permitting extension to slide onto case.
18. Install the extension-to-case bolts, tightening to 35-45 ft. lbs., and 2 extension-to-retainer bolts, tightening to 20 - 30 ft. lbs. Use suitable sealer on lower right attaching bolt (viewed from rear). Due to a change in the case on 1962 this is no longer necessary.

Fig. 8 Four speed manual shift transmission. 1958-62 Chevrolet

19. Adjust reverse shifter shaft so that groove in shaft lines up with hole in boss and drive in lock pin from top of boss.
20. Install main drive gear bearing retainer and gasket, making certain oil well lines up with oil outlet hole. Install bolts with suitable sealer and tighten to 15-20 ft. lbs.
21. Install a shift fork in each clutch sleeve. With both clutches in neutral, install side cover and gasket. Tighten cover bolts evenly to 10-20 ft. lbs. torque. Use suitable sealer when installing lower right bolt. Install shift levers.

GEARSHIFT, ADJUST

1955

In cases where the gearshift linkage has been disconnected, it should be adjusted when reconnecting as follows:

Slide the shifter rods into their respective swivel fittings on the levers at the control tube. Move the shifter rods through the swivel fittings until the transmission is in neutral and the 1st and reverse lever is at the midpoint of its travel (center of slot). Align the 2nd and 3rd shifter lever with 1st and reverse lever and tighten swivel fitting nuts. *Shifter tube levers must be in line or key will not enter keyway in levers.*

1956-57

Whenever the gearshift linkage has been disconnected, it should be readjusted as follows:

Fig. 9 Construction of keyway tool for adjusting gearshift lever. 1956-57 with synchromesh transmission

Loosen swivel nuts and insert tool shown in Fig. 9 in the keyway in the adjusting ring at the bottom of the mast jacket through 1st and reverse lever and 2nd and high lever. Move both control rods until transmission is in neutral. Neutral detents must both be engaged to make this adjustment correctly. To check, start engine with clutch disengaged, and release clutch slowly. Tighten swivel nuts and remove aligning tool.

1958-62 Three Speed

1. Move both control rods until transmission is in neutral. Neutral detents in transmission cover must both be engaged to make this adjustment correctly. To check, start engine with clutch disengaged, and release clutch slowly.
2. Move selector lever to neutral position. Engage second and third shifter lever on tube with relay lever.
3. Center levers in mast jacket by measuring from edge of slot in jacket to edge of slot in spacer at each side of lever.
4. Adjust swivel on end of second and third shifter control rod until swivel enters hole in lever. Install swivel and insert retaining clip.

Fig. 10 Four speed manual shift transmission gearshift linkage. 1958-62 Chevrolet

5. Move first and reverse lever on tube until lug on lever lines up with slot in relay lever. Pull relay lever to make sure lug will mate with slot.
6. Adjust swivel on end of first and reverse shifter control rod until swivel enters hole in lever. Install swivel and insert retaining clip.
7. Move selector lever through all positions to check adjustment and to insure over-travel in all positions.

1960-62 Four Speed Trans.

As shown in Fig. 10, a simple gauge block, locally made to the specifications indicated, will aid in making the proper adjustments. The adjustments can be made without the gauge block by having an assistant hold the manual shift lever in neutral position.

1. Referring to Figs. 10 and 11, remove gearshift lever seal from floor pan.
2. Place transmission in neutral and, if gauge block is used, position in slot.
3. Remove clevis pin at each shift lever.
4. On each shift rod, adjust threaded clevis to permit free entry of pin into hole in transmission shift lever.
5. Connect clevises to levers.
6. Remove gauge block and check shifts. If any roughness exists, one of the clevises may require adjustment of about ½ turn. Determine the rod and clevis requiring adjustment by sighting along the slot where the gauge block was used. *If transmission is removed from car, shift linkage should be adjusted before transmission is reinstalled.*

Fig. 11 Four speed manual shift transmission gearshift linkage adjustments. 1958-62 Chevrolet

AUTOMATIC TRANS.

A detailed description and service procedure on these transmissions is given in the *Automatic Transmission Section* of this manual. Service adjustments and replacement procedure follows:

NEUTRAL SAFETY SWITCH

1955-56

Loosen one of the switch mounting screws and remove the other. Place selector lever in neutral. Center visible elongated slot in switch mounting with tapped hole in mast jacket. Then tighten screw that was loosened and tighten screw that was removed.

If the engine will not turn over after the switch is positioned as directed above, loosen the screws and rotate the switch until it does.

1957

Loosen both the switch mounting screws. Place selector lever in Neutral. Install cotter pins or similar aligning pins into two holes in switch on each side of pointer. Switch may be rotated to pointer between holes. Tighten the screws and remove cotter keys. *The slot in the switch must be set on the center line of the tang on the shifter tube.*

If, after the switch is positioned, the engine will not turn over, loosen the

Fig. 13 Adjusting 6-cylinder throttle linkage. 1955 Powerglide

Fig. 15 Adjusting 6-cylinder throttle linkage. 1956-57 Powerglide

screws and rotate the switch in the direction necessary until it does. Be sure selector lever is in Neutral when performing this operation.

1958-62 Chevrolet

Place selector lever in Neutral. Loosen screws securing switch retainer, then while holding ignition switch in "Start," adjust position of switch until engine starts cranking. Hold switch in this position and tighten screws.

Chevy II

1. To adjust switch position, place shift lever in neutral.
2. Loosen screws securing switch retainer. Then while holding ignition switch in "Start" position, adjust position of switch until engine turns over.
3. Hold switch in this position and tighten retainer screws.
4. Check adjustment by testing for cranking in both Neutral and Park.

LINKAGE, ADJUST

Positive Linkage, 1955-57

1. Loosen shifter tube lever clamp nut enough to allow upper control rod to move freely in the swivel.
2. Push the control bell crank (left side of transmission case) toward the front of the car as far as it will go. This places the transmission in the Park position.
3. Place shift control lever (on steering column) in Park position.
4. Tighten shifter tube lever clamp nut securely.

Fig. 14 Use of outer throttle valve lever gauge. 1955-56 Powerglide (6-cyl.)

Throttle Valve Linkage, 1955 Six

1. With selector lever in Drive Range and hand brake set, adjust engine idle to 425 rpm with engine at normal operating temperature and transmission warm.
2. After setting idle, shut off engine.
3. Disconnect rod "C", Fig. 13, from throttle lever "E".
4. Remove the extreme lower bolt from the rear low and drive body cover.
5. Rotate throttle valve control outer lever assembly counterclockwise to the open throttle position (to a definite stop). Hold in this position and, with the gauge shown in Fig. 14 set at 6⅜", measure distance between hole in side cover and hole in throttle lever. If the gauge pins will enter holes, adjustment of lever "E" is correct. If adjustment is not correct, loosen lever-to-clamp attaching bolt and adjust outer lever as necessary.
6. Connect rod "C" to lever "E".
7. Disconnect rod "B" from carburetor throttle valve lever and rod "D" from accelerator and throttle valve lever on cylinder block.
8. With engine idle set as in Step 1 and rod "C" forced forward against stop in transmission (open throttle), adjust rod "B" for free entry of swivel pin in carburetor throttle valve lever, with carburetor throttle valve in wide open position.
9. With carburetor throttle valve held in wide open position, and accelerator pedal fully depressed, adjust rod "D" for length required for free entry of swivel pin in bell crank.

Throttle Valve Linkage, 1956-57 Six

1. With selector lever in Drive and hand brake set, adjust engine idle to 425 rpm with engine and transmission at operating temperature.
2. After setting idle, shut off engine.
3. Disconnect rod C from lever B, Fig. 15.
4. Remove lower rear bolt from transmission side cover.
5. Rotate lever A counterclockwise to the full detent position. Hold in this position and, with gauge shown in Fig. 14 set at 7.09", measure distance between hole in side cover and hole in lever B. If gauge pins enter holes, adjustment of lever B is cor-

Fig. 16 Adjusting V8 throttle linkage. 1955 Powerglide

rect. If not, loosen clamp A and adjust lever as necessary.
6. Install rod C.
7. Disconnect rod E from carburetor throttle valve lever, and rod G from accelerator and throttle valve lever on cylinder block.
8. Move lever F to the wide open position and adjust rod E for free entry into lever D.
9. With accelerator pedal depressed placing lowest point on accelerator rod 1" above toe panel, and lever D rotated to the wide open position, adjust rod G for free entry of swivel pin in accelerator bell crank.
10. Check adjustment by releasing and depressing accelerator pedal. If lever F does not reach the wide open position it will be necessary to repeat Steps 8 and 9.

Throttle Valve Linkage, 1955 V8

1. With engine and transmission warm and set to idle at 425 rpm, shut off engine.
2. Disconnect rod "F" from throttle lever "E", Fig. 16.
3. Remove bolt from extreme lower rear low and drive body cover.
4. Rotate throttle valve control outer lever counterclockwise to the open throttle position (to a definite stop). Hold in this position and with the gauge shown in Fig. 17 set at 2⅞", measure the distance between the hole in the side cover and hole in throttle lever, Fig. 17. If pins of gauge will enter holes, adjustment of lever "E" is correct. If adjustment is not correct, loosen lever-to-clamp attaching screw and adjust the clamp as necessary.
5. Connect rod "F" to lever "E".
6. Disconnect rods "B" and "G" from carburetor throttle valve lever.
7. With engine idle set as recommended and rod "F" forced forward against stop in transmission, adjust rod "G" for free entry of swivel pin in carburetor throttle valve lever with carburetor throttle valve in wide open position.
8. With throttle in wide open position and accelerator pedal fully depressed, adjust rod "B" for free entry of swivel pin in throttle valve lever.

Fig. 17 Use of outer throttle valve lever gauge. 1955-57 Powerglide (V8)

Throttle Valve Linkage. 1956 V8 With Powerglide and 2-Barrel Carburetor

1. With engine and transmission at operating temperature, set idle at 425 rpm and shut off engine.
2. Disconnect rod C from lever B, Fig. 18.
3. Remove bolt from lower rear hole of transmission left hand side cover.
4. Rotate clamp A counterclockwise to full detent position. Hold in this position and, with gauge shown in Fig. 17 set at 2.88", measure distance between hole in side cover and hole in lever B. If pins of gauge enter holes freely the adjustment is correct. If not, loosen clamp A and adjust as necessary.
5. Connect rod C to lever B.
6. Disconnect rods G and E from lever F.
7. Rotate lever F to wide open position and adjust rod E to enter freely while holding it forward against transmission internal stop.
8. With accelerator pedal depressed, placing lowest point on accelerator rod ¾" above toe panel, and lever F rotated to wide open position, adjust rod G for free entry into lever F before attaching it.
9. Check adjustment by releasing and depressing accelerator pedal. If lever F does not reach the wide open position it will be necessary to repeat Steps 7 and 8.

Throttle Valve Linkage. 1956 V8 With Powerglide and 4-Barrel Carburetor

1. With engine and transmission at operating temperature, set idle at 425 rpm and shut off engine.
2. Disconnect rod G from lever E, Fig. 19.
3. Remove bolt from lower hole of transmission left hand side cover.
4. Rotate clamp F counterclockwise to the full detent position. Hold in this position and, with the gauge shown in Fig. 17 set to 2.88", measure the distance from the hole in the side cover to the hole in lever E. If pins of gauge enter holes freely, adjustment is correct. If not, loosen clamp F and adjust as necessary.
5. Install rod G.
6. Disconnect rod B from lever J and rod H from lever K.
7. Place lever J to wide open position and pull rod G upward until it is stopped by transmission internal stop. Adjust rod H for free entry into lever K.
8. With accelerator pedal depressed, placing lowest point on accelerator rod 1" above toe panel, and lever J rotated to wide open position, adjust rod B for free entry into lever J.
9. Check adjustment by releasing and depressing accelerator pedal. Lever J should reach wide open position.

Fig. 18 Adjusting V8 (2-barrel carb.) throttle linkage. 1956 Powerglide

Fig. 19 Adjusting V8 (4-barrel carb.) throttle linkage. 1956 Powerglide

Fig. 20 Throttle linkage adjustment. 1957 V8 Powerglide

Fig. 21 Shift linkage adjustment. 1958-62 Powerglide with cast iron case

If not it will be necessary to repeat Step 8.

Throttle Linkage, Adjust 1957 V8 Powerglide

1. Referring to Fig. 20, remove rod C.
2. Loosely assemble lever B to clamp A.
3. With suitable gauge in place so as to obtain the 3⅝" dimension between the points indicated in Fig. 20, tighten lever B to clamp A.
4. Install rod C.
5. Install rod E in cross shaft D.
6. Place lever F in wide open position and pull rod E forward until it is stopped by transmission internal stop. Adjust swivel in rod E for easy entrance in lever F before fixing swivel in lever F.

Shift Linkage, 1958-62

1. With engine stopped, lift up on range selector lever and move the lever to the position where transmission Drive detent is felt, Fig. 21. Slowly release lever to see if lever lock pin freely enters lock plate. Check Reverse range in similar manner. If the lock pin does not freely enter the lock plate in both Drive and Reverse ranges, adjust as follows:
2. Place range selector lever in Drive. Loosen clamp nut on shift control rod at attachment to the shift control lever on the lower end of the mast jacket.

Fig. 22 Throttle linkage adjustment 1958-61 Six-cylinder Powerglide with cast iron case

Fig. 23 Throttle linkage adjustment. 1958-62 V8 Powerglide with cast iron case

Fig. 24 Throttle linkage adjustments. Chevy II

Fig. 25 Shift linkage adjustments. 1962 Aluminum Powerglide

3. Hold shift control lever (at lower end of mast jacket) against the Drive stop of the range selector lock plate while at the same time adjusting the length of the shift control rod to obtain Drive detent at the transmission. With the linkage held in this position, carefully retighten the clamp nut on the shift control rod. *Drive detent in the transmission is the second detent felt as the shift lever is pulled forward from its rearmost travel.*

Throttle Linkage, 6-Cyl.

1. Referring to Fig. 22, loosely assemble lever B to clamp A.
2. Insert Gauge J-5906 between transmission left hand side cover lower rear bolt and hole in lever B. Dimension between bolt and hole center lines should be 7.09 inches as shown in Fig. 22. With gauge in place, and holding clamp A counterclockwise in full detent position, tighten lever B to clamp A. Remove gauge.
3. Install rod C.
4. Install rod E in lever D. Place lever F in wide open position and pull rod E up until it is stopped by transmission internal stop. Adjust swivel in rod E for free entry in lever F before fixing swivel in lever F.
5. Check adjustment by placing linkage in idle position, then return to wide open. Position by rotating lever F upward on lever B to see if rod C deflects, meaning transmission is not on internal stop. If rod deflects, or lever F will not reach wide open position, repeat Step. 4.
6. With accelerator pedal depressed until lever H contacts stop and lever D rotated to wide open position, adjust swivel or rod G for free entry into lever D before fixing swivel to lever D.
7. Check adjustment by releasing, then depressing, accelerator pedal. Check lever F for wide open position; if it doesn't reach repeat Step 6.

Throttle Linkage, V8

1. Referring to Fig. 23, loosely assemble lever B to clamp A.
2. Insert Gauge J-5906 between transmission left hand side cover lower front bolt and hole in lever B. Distance between hole center lines is 3.60″, Fig. 23. With gauge in place and holding clamp A counterclockwise in full detent position, tighten lever B to clamp A. Remove gauge.
3. Install rod C.
4. Install rod E in cross shaft D. Place lever F in wide open throttle position, adjust rod swivel on rod E for free entry in throttle bellcrank, *and then lengthen the adjustment by three turns.* Fasten swivel in bellcrank.
5. Check the adjustment by releasing linkage to its idle position, then rotate throttle bellcrank F to wide open position. While holding linkage thus, press downward on transmission outer TV lever B and check for deflection. If rod C deflects, repeat Step 4.
6. Place a ½″ wood block beneath accelerator pedal rod, depress and hold accelerator to block and then adjust swivel on rod G for free entry into throttle bellcrank F with bellcrank held fully wide open.
7. Remove wood block and depress accelerator pedal by hand to check for detent feel and check that throttle bellcrank F reaches wide open position; if it doesn't reach, repeat Step 6.

1962 STD. P.G.

Transmission shift linkage and throttle linkage adjustments with the standard Powerglide (cast iron case) used on six-cylinder and V8-283 vehicles remain the same as 1961.

ALUMINUM CASE POWERGLIDE, 1962

Throttle Linkage, Chevy II

1. With accelerator pedal depressed and dash lever "A" (Fig. 24) against a .060″ spacer on the lever stop, rotate bellcrank "B" to wide open position.
2. Adjust swivel on rod "C" so it freely enters hole in bellcrank "B".
3. Rotate bellcrank "B" and rod "C" to wide open position against spacer and lever stop.
4. Assemble rod "D" in transmission lever "E" and push on rod "D" to reach full detent at the transmission.
5. Adjust swivel on rod "D" to freely enter hole in bellcrank "B".

Shift Linkage, Chevrolet

1. Check transmission shift linkage for proper adjustment as follows: With engine stopped, lift up on range selector lever and move the lever to the position where transmission "Drive" detent is felt. Slowly release the lever to feel if the shaft lever tang freely enters the lock plate. Check "Reverse" range in a similar manner. If the tang does not freely enter the lock plate in both "Drive" and "Reverse" ranges, it will be necessary to perform the linkage adjustments given in the following steps.
2. Position range selector lever in "D". Disconnect shift control rod at its swivel attachment to the shift control lever on the lower end of the mast jacket by loosening the clamp nut.
3. Place transmission shift control

outer lever, Fig. 25, in Drive position.
4. Hold shift control lever (at lower end of mast jacket) against drive stop of range selector lock plate and with control rod through swivel, tighten clamp nut.
5. Test transmission in all ranges.

Throttle Linkage, Chevrolet

1. Referring to Fig. 26, install rod "C".
2. Thread one end of rod "E" about halfway through swivel and install other end in lever "F".
3. Place lever "F" in wide open position and move cross shaft assembly "D" forward until stopped by transmission internal stop. Adjust swivel on rod "E" until swivel freely enters cross shaft "D". Fix swivel in cross shaft.
4. Check adjustment by placing linkage in idle position, then return to wide open position by rotating lever "F". Push downward on lever "B" and note if rod "E" deflects, indicating that the transmission is not on the internal stop. If rod deflects or lever "F" will not reach wide open throttle position, repeat above adjustment.
5. Depress accelerator pedal until lever "H" contacts the .125" spacer. Rotate lever "F" to wide open position. Then adjust swivel in rod "G" for free entry into lever "F" and install rod into lever.
6. Check adjustment by releasing, then depressing the accelerator pedal. Check lever "F" for wide open position. Repeat Step 5 if lever will not reach wide open position.

Neutral Safety Switch

1. Place gearshift lever in "N".
2. Loosen screws securing switch retainer. Then while holding ignition switch in "Start", adjust position of switch until engine turns over.
3. Hold switch in this position and tighten retainer screws.

Transmission, Replace

1. Disconnect oil cooler lines, vacuum modulator line and speedometer drive cable at transmission. Tie lines out of the way.
2. Unfasten crankcase ventilation tube clamp bracket.
3. Disconnect linkage at transmission.
4. Disconnect propeller shaft.
5. Attach suitable lifting equipment to transmission.
6. Remove transmission support crossmember. *Use care to remove shims that may be present between extension mounting boss and crossmember. It is vital that same number of shims be reinstalled as these effect drive line angles.*
7. Remove converter underpan, scribe flywheel-converter relationship for assembly, then remove attaching bolts. *This is important to maintain balance on assembly.*
8. Support engine at oil pan rail with a jack or other suitable brace capable of supporting engine while transmission is removed.
9. Lower rear of transmission slightly so that upper transmission housing-to-engine bolts can be reached using a universal socket and long extension. Remove upper bolts. *Caution: On V8 engines, use care when lowering rear of transmission to see that distributor housing is not forced against dash.*
10. Remove remaining attaching bolts. Then move transmission slightly to the rear and downward out of chassis. *When moving transmission rearward observe converter; if it does not move with the transmission, pry it free of flywheel before proceeding. Keep front of transmission upward to prevent converter from falling out. Use a length of strong wire to keep it attached to the transmission while being removed.*
11. Reverse foregoing procedures to install transmission.

Fig. 26 Throttle linkage adjustments. 1962 Aluminum Powerglide

POWERGLIDE, REPLACE

1958-61

1. Drain transmission oil and remove filler pipe.
2. Disconnect oil cooler lines, vacuum modulator hose and speedometer drive cable fitting at transmission. Tie lines out of the way.
3. Disconnect body ground strap.
4. Disconnect control rods at transmission.
5. Remove propeller shaft.
6. Attach suitable transmission lifting device.
7. Disconnect engine rear mount on transmission extension, then remove transmission support crossmember.
8. Remove flywheel cover and flywheel-to-converter attaching bolts.
9. Lower rear of transmission slightly so that three upper transmission attaching bolts can be reached; use universal socket and a 39-inch extension. *Care must be taken not to lower transmission too far as the distributor housing may be forced against the dash causing damage to the distributor.*
10. Support engine at oil pan rail with a suitable jack capable of supporting weight of engine when transmission is removed.
11. Remove remaining transmission attaching bolts.
12. Move transmission slightly to the rear and downward. *Do not tip front of transmission downward as the converter could fall out as transmission is removed.* Secure converter in place with a suitable holding tool to prevent it falling out.
13. Reverse removal procedure to install transmission.

Removal, 1955-57

1. Remove toe pan plate.
2. Remove spark plugs.
3. On V8s, disconnect ground strap from battery and wires from starter solenoid.
4. Disconnect oil cooler lines at transmission and speedometer cable from driven gear fitting. Unclip cooler lines and tie them to right frame side rail.
5. Disconnect transmission control rods from levers.
6. On 1955-57 models, split rear universal joint and remove propeller shaft and front universal joint.
7. Drain transmission. Remove filler tube and dip stick and tape filler tube opening.
8. On V8s, remove starting motor.
9. On V8s, disconnect exhaust pipe from cross-over pipe. On 6-cylinder models, disconnect exhaust pipe from exhaust manifold.
10. Disconnect muffler from its bracket. Then move exhaust pipe and muffler to the left and tie to left frame side member.
11. Remove flywheel inspection cover.
12. Using a suitable tool to turn engine over, remove three flywheel-to-converter attaching bolts through opening in flywheel housing that is adja-

Fig. 27 Shift linkage adjustment. 1958 Turboglide. Typical of 1959-61

Fig. 28 Throttle linkage adjustment. 1958 Turboglide

cent to the starting motor on V8s. On 6-cylinder models, the opening is on left side of engine.

13. Remove all converter housing-to-flywheel housing bolts except the upper most three.
14. Install engine support bar or cradle to support engine.
15. Position hydraulic jack under transmission; raise and fasten handling equipment to transmission.
16. Remove rear engine mountings.
17. Remove three remaining attaching bolts through toe pan opening.
18. Move transmission to rear slightly and install a suitable converter holding tool.
19. Lower transmission on jack and remove from under car.
20. Reverse the order of removal procedure to install the transmission.

TURBOGLIDE

For details on this transmission see the *Turboglide Chapter*.

TURBOGLIDE LINKAGE

1959-61 Adjustments

Shift Linkage—

1. Check transmission shift linkage for proper adjustment as follows: With engine stopped, move range selector lever to the position where Drive detent is felt. Slowly release lever to feel if lever lock pin freely enters lock plate. Check Reverse range in similar manner. If lock pin does not enter lock plate freely in both ranges, adjust as follows:
2. Position selector lever in "D". Disconnect shift control rod at its swivel attachment to the shift control lever on the lower end of the mast jacket by loosening clamp nut.
3. Place transmission shift control outer lever in Drive Position. (Drive detent in transmission is the first clockwise detent position from the fully counterclockwise detent or "GR" position, Fig. 27.
4. Hold shift control lever (at lower end of mast jacket) against the Drive stop of the range selector lock plate while at the same time adjusting the length of the swivel on the shift control rod for free entry into the shift lever on the mast jacket. With the linkage held in this position, carefully retighten the swivel clamp nut.
5. Test transmission shifts in all ranges.

Throttle Detent Linkage—

1. Disconnect transmission throttle rod from carburetor throttle lever and accelerator rod from carburetor throttle lever.
2. Pull throttle valve rod toward front of car its full limit of travel, then adjust TV rod swivel for free entry into carburetor throttle lever with lever in wide open throttle position. Secure swivel to lever.
3. Check adjustment by placing carburetor throttle lever in wide open position, then pushing downward (counterclockwise) on transmission throttle valve lever and noting if transmission throttle valve rod attached to carburetor throttle lever deflects (transmission not on internal stop). If rod deflects or carburetor throttle lever will not reach wide open position, repeat adjustment.
4. Position carburetor throttle lever at wide open throttle and with an assistant depressing the accelerator pedal to hold the accelerator pedal lever in contact with the lever stop, adjust swivel on accelerator rod to permit free entry into carburetor throttle lever. Secure swivel to lever.
5. Check for detent feel by depressing accelerator pedal by hand. Detent should be felt before accelerator pedal rod strikes carpet or floor mat.

Neutral Safety Switch—

1. Place gearshift lever in neutral.
2. Loosen screws securing switch retainer. Then while holding ignition switch in "Start", adjust position of switch until engine turns over.
3. Hold switch in this position and tighten screws.
4. Check adjustment by cranking in both neutral and park.

1958 Adjustments

Shift Linkage—Follow instructions as outlined for 1959 models.

Throttle Linkage—

1. Disconnect transmission throttle valve (TV) rod at throttle bellcrank on carburetor.
2. Place wood block ½" thick beneath accelerator pedal rod and carpet or floor mat and have an assistant hold accelerator pedal fully down to block.
3. Pull transmission TV rod toward front of car its full limit of travel (through detent) and adjust rod swivel for free entry into hole in throttle bellcrank, Fig. 28.
4. Connect TV rod swivel to throttle bellcrank with clip, remove block from beneath accelerator pedal rod and check for detent "feel" by depressing accelerator pedal by hand. Transmission detent should be felt before pedal rod strikes carpet or floor mat.
5. Road test and adjust to insure that stator high angle is obtained at full throttle.

Neutral Safety Switch—This adjustment is obtained in the same manner given for 1959.

1957 Adjustments

Shift Linkage—

1. Loosen shifter tube lever clamp nut to allow upper control rod to move freely on the swivel.
2. Move selector lever on transmission toward front of car to Neutral position (3rd position forward).
3. Place hand control lever in Neutral.
4. Tighten shifter tube swivel clamp nut.
5. Check operation of linkage.

Throttle Linkage—

1. Referring to Fig. 21, remove rod A from throttle lever B.
2. Place lever B in wide open position and pull rod A forward until stator control valve spring tension is overcome and lever is bottomed.
3. Adjust swivel on rod A for easy entrance in lever B before fixing swivel in lever B.

Neutral Safety Switch—

1. Loosen switch mounting screws.

2. Place selector lever in neutral.
3. Install cotter keys into two holes in switch on each side of pointer. Switch may be rotated to place pointer between holes.
4. Tighten mounting screws and remove cotter keys.
5. If engine does not turn over after adjustment is made, loosen screws and rotate switch in the direction necessary until it does. Be sure selector lever is in neutral when performing this operation.

TURBOGLIDE, REPLACE

1957

1. Remove toe pan plate.
2. Remove spark plugs.
3. Disconnect battery ground strap from battery and wires from starter solenoid.
4. Remove starter.
5. Remove oil filler pipe.
6. Disconnect oil cooler lines at thermal by-pass valve, remove hose from diaphragm and remove speedometer cable. Tie cooler lines to right frame side rail.
7. Disconnect linkage rods from transmission levers.
8. Remove propeller shaft and front universal joint.
9. Drain transmission fluid.
10. Disconnect muffler from its support bracket and move muffler and exhaust pipe to the left and tie to left frame side member.
11. Remove converter underpan.
12. Support rear of engine with a jack.
13. Unfasten flywheel from converter.
14. Place separate jack under transmission.
15. Remove both rear engine mounts.
16. Unfasten transmission from engine.
17. Move transmission to rear slightly and install a suitable converter holding tool.
18. Lower transmission from under car.
19. Reverse foregoing procedure to install the transmission.

1958

1. Drain oil and remove filler pipe.
2. Disconnect oil cooler lines and speedometer drive cable fitting at transmission. Tie lines out of the way.
3. Disconnect body ground strap.
4. Disconnect shift control rods from transmission.
5. Remove propeller shaft.
6. Attach a suitable transmission lifting device.
7. Disconnect engine rear mount on transmission extension and remove transmission support crossmember.
8. Remove flywheel cover and flywheel-to-converter attaching bolts.
9. Lower rear of transmission slightly so that three upper transmission-to-engine attaching bolts can be reached (use a universal socket and a 39" extension). *Care must be used not to lower the transmission too far as the distributor housing may be forced back against the dash causing damage to the distributor.*
10. Support engine at oil pan rail with a jack capable of supporting engine when transmission is removed.
11. Remove remaining attaching bolts.
12. Move transmission slightly to rear and downward and out beneath car. *Do not tilt front of transmission downward as the converter may fall out.*
13. To install, reverse removal procedure.

1959-61

1. Remove drain plug (early) or filler tube (late) to drain oil.
2. Disconnect oil cooler lines and speedometer cable.
3. Remove crankcase ventilation clamp from transmission.
4. Remove hose from vacuum modulator and from clamped attachment at side of transmission.
5. Disconnect rods from levers at transmission.
6. Disconnect propeller shaft from transmission.
7. Install suitable transmission lifting rig or other lifting device.
8. Disconnect engine rear mount on transmission extension, then remove transmission support crossmember. *If shims are present, be sure to reinstall exactly the number present as these effect drive line angles.*
9. Remove transmission underpan.
10. Mark flywheel-to-converter relationship for assembly. Then, using a jumper to turn over engine, remove flywheel-to-converter attaching bolts. *The "light" side of converter is denoted by a "blue" stripe painted across the ends of the converter cover and housing. This marking should be aligned as closely as possible with the "white" stripe painted on the engine side of the flywheel outer rim to maintain balance during assembly.*
11. Lower transmission slightly so that 3 upper transmission attaching bolts can be reached for removal. *Do not lower transmission too far as there is danger of the ignition distributor housing being forced against the dash.*
12. Support engine with jack at oil pan rail while transmission is removed.
13. Remove remaining attaching bolts and remove transmission from vehicle.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

1955-62 REAR AXLE

The drive pinion is mounted on preloaded taper roller bearings, Fig. 1. Adjustment of the pinion along its axis is obtained by a shim placed between the rear bearing inner race and pinion. Adjustment of preload of the two bearings is obtained by tightening the companion flange nut which compresses a spacer over the pinion stem between the bearings. Both bearing outer races are pressed into the carrier.

Axle Shaft, Replace

Caution—Several types of ball and roller bearings have been used. Some ball bearings have the seal mounted outboard as shown in Fig. 2, while others have the seal mounted inboard as shown in Fig. 3. These various installations cannot accurately be applied to specific car models. Therefore, when necessary to replace a bearing, examine the installation carefully and, if the new bearing is identical with the old, install it the same

Fig. 1 Rear axle. 1955-62. Chevy II pinion bearing spacer is much shorter than Chevrolet. However, long spacer shown can be used for service

Fig. 2 Axle shaft and bearing with seal mounted outboard

way. However, should a roller bearing be installed where the original bearing was a ball type (or vice versa) follow the installation instructions contained in the bearing package.

1. To remove an axle shaft, take off rear wheel, brake drum and gasket.
2. Remove four nuts and washers from bearing retaining bolts on inside of axle flange, Fig. 2.
3. Use a suitable puller and pull out axle shaft and bearing. Be careful not to disturb the brake backing plate. If bearing retainer and parking brake strut interfere, raise strut slightly with screw driver to obtain clearance.
4. Install bolt and nut to retain brake backing plate on axle housing.

Differential Carrier, Replace

1. Remove axle shafts. They need only to be pulled out far enough to clear differential side gears.
2. Split rear universal joint and lower propeller shaft to floor. Tape bearings to trunnion.
3. Remove nuts which fasten differential carrier to axle housing.
4. Place a drip pan under housing and slightly separate carrier and housing and allow lubricant to drain. When drained, remove differential carrier.
5. Reinstall in the reverse order of removal.

Rear Axle Repairs

In these axles, the threaded nut type of differential is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations are given in the *Rear Axle Chapter*.

The following procedure outlines the method of setting up of the drive pinion and bearings.

Pinion & Bearings, Replace

After removing the differential unit from the carrier, unscrew the pinion flange retaining nut and pull off the flange. Press the pinion out of the front bearing and through the rear end of the carrier. The rear bearing cone, shim and bearing spacer will come out with the pinion. The bearings may then be removed and installed with suitable pulling equipment.

Reverse the operations to assemble and, after pressing on the pinion flange, slip on the washer and nut. Tighten the nut until the bearings have a preload drag of 15 to 25 inch pounds to rotate the pinion shaft.

To adjust the preload, draw up the nut until the spacer starts to buckle. Check the pull with a torque wrench or with a spring scale. This adjustment must be made every time the flange nut is removed or loosened. If the adjustment is to be made with the differential unit in the carrier, the rear wheels must be jacked off the floor.

The pinion can be moved in toward the center of the axle by installing a thinner shim. If it is to be moved away from the center of the axle, use a thicker shim.

Note—A new spacer is required between the pinion bearings when a new ring gear and pinion set is installed, either outer or inner members of either pinion bearing is changed, a new carrier casting used, or pinion adjusting shim thickness is increased. When the same pinion flange is removed and reinstalled as when an oil seal is replaced, checking for pinion bearing preload with a torque wrench is not necessary if care is taken to tighten the nut exactly to its previous position. Should a new pinion flange be required, a torque wrench reading should be taken before loosening the nut and the nut tightened to the same torque wrench reading.

MASTER CYLINDER, REPLACE

1955-57

To remove master cylinder, disconnect the hydraulic line from the end of the cylinder and remove the bolted brass fitting. Unfasten the cylinder from the dash panel and lift it off.

Reverse the above procedure to install the cylinder, fill the reservoir with brake fluid and bleed the system as outlined in the *Hydraulic Brake System Chapter*.

1958-62

To remove the master cylinder, disconnect the hydraulic line from the end of the cylinder. Remove clevis pin from brake pedal arm. Unfasten master cylinder from dash panel and remove from vehicle.

Fig. 3 Axle shaft and bearing with inboard mounted seal

Reverse the above procedure to install the cylinder, fill the reservoir with brake fluid and bleed the system as outlined in the *Hydraulic Brake System Chapter*.

POWER BRAKE UNIT

Repairs on the power brake unit are contained in the *Power Brake Chapter*. To remove and install the unit, proceed as follows:

1955-58

1. On engine side of dash panel, remove vacuum lines from vacuum inlet tube on intake manifold.
2. Remove vacuum line to vacuum reservoir.
3. Remove stop light wire (1955-57).
4. Remove hydraulic line from hydraulic cylinder.
5. From inside car body, disconnect lever from push rod.
6. Unfasten and remove power unit from dash panel.
7. Reverse the foregoing procedure to install the unit.

1959-62

1. Disconnect clevis at brake pedal.
2. Remove hoses from power unit.
3. Disconnect hydraulic line from master cylinder.
4. Unfasten and remove power unit from dash.
5. Installation is made in the reverse order of removal.

POWER BRAKE SYSTEM, BLEED

1954-62

The power brake system may be bled in the conventional manner as outlined in the *Hydraulic Brake System Chapter*.

Front End and Steering Section

CHEVY II WHEEL ALIGNMENT

Caster, Adjust

Caster is adjusted by turning the two nuts at the front of the lower control arm strut rod. Shortening this rod will increase caster; lengthening the rod will decrease caster.

Camber, Adjust

Camber is adjusted by loosening the lower control arm pivot bolt and rotating the cams on this pivot, Fig. 1. This eccentric cam action will move the lower control arm in or out, thereby varying camber.

Toe-In, Adjust

Toe-in can be adjusted by loosening the clamp bolts at each end of each tie rod and turning each tie rod to increase or decrease its length as necessary until proper toe-in is secured and the steering gear is in its mid-position for straight ahead driving.

Fig. 2 Chevy II upper control arm support installed. Right side control arm support bracket is shown. For left side, angled support should be welded to reverse side of plate

CORVETTE WHEEL ALIGNMENT

Caster and camber adjustments are both performed by turning the upper control arm pivot pin. The pivot pin has a $\frac{3}{32}$ in. eccentric. To make the adjustment, proceed as follows:

1. Loosen the clamp bolt at the upper end of the steering knuckle support.
2. Remove grease fitting from the rear bushing.
3. Insert an Allen set screw wrench through the hole from which the grease fitting was removed.
4. Turn the pivot pin in the direction to obtain an exact caster setting. The camber may remain practically the same or it may move in a positive or negative direction, depending on the location of the eccentric on the pivot pin.
5. After making a slight turn of the pivot pin, both caster and camber must be rechecked and adjustments made that will bring both angles within the limits.

Toe-in is adjusted by loosening the clamp bolts at each end of the left-hand tie rod and turn this rod as required to obtain correct toe-in.

Fig. 1 Chevy II lower control arm pivot components. Cams are for adjusting camber angle

CHEVROLET WHEEL ALIGNMENT

The caster and camber adjustments are made by means of shims between the upper control arm inner support shaft and the support bracket attached to the frame side rail. Shims may be changed at either the front of the shaft or the rear of the shaft to change caster or at both points equally to change camber.

The addition of shims at the front bolt or removal of shims at the rear bolt will decrease positive caster. A $\frac{1}{32}$" shim difference (one shim) will change caster ¼°. Adding shims at both front and rear of support shaft will decrease positive camber. A $\frac{1}{32}$" shim change will move camber $\frac{1}{16}$°.

The adjustment procedure is to loosen the upper support shaft-to-bracket bolts, add or remove shims as required and retighten the bolts. *Both caster and camber can be performed in one operation.*

Toe-In, Adjust

Toe-in can be adjusted by loosening the clamp bolts at each end of each tie rod and turning each tie rod to increase or decrease its length as necessary until proper toe-in is secured and the steering gear is on the high point for straight-ahead driving.

WHEEL BEARINGS, ADJUST

Chevy II

1. Tighten spindle adjusting nut to 100 inch pounds while rotating wheel.
2. Back off nut one flat (1/6 turn).
3. Insert cotter pin if slot in nut and hole in end of spindle align. If not, back off nut an additional ½ flat (1/12 turn) or less and insert cotter pin.
4. Spin wheel to make certain that it rolls freely. Properly lock cotter pin. *These tapered roller wheel bearings should have zero preload and from .000" to .004" end play when properly adjusted.*

1961-62

Chevrolet & Corvette

To adjust the bearings, tighten the spindle nut to 15 ft. lbs. torque while rotating the wheel. Then back off one flat and install cotter pin. If cotter pin hole does not line up with nut slot, continue to back off nut just enough to install cotter pin.

1955-60

Tighten spindle nut to 28 ft. lbs. torque and rotate wheel to seat bearings. Back off adjusting nut until bearings are loose and then re-torque to 12 ft. lbs. If cotter pin cannot be inserted, back off nut just enough to permit pin to be inserted.

CHECKING BALL JOINTS FOR WEAR

Chevy II

The upper ball joint is a loose fit when not connected to the steering knuckle. Wear may be checked without disassembling the ball stud by using the following procedure:

1. While vehicle weight is still on front wheels, insert upper control arm support as shown in Fig. 2.
2. Raise vehicle and allow wheel and tire to hang free.
3. Measure distance from tip of ball stud to top surface of control arm.
4. Place adjustable jack under tire and raise slightly to take up ball joint looseness.
5. Repeat Step 3 if difference in measurement exceeds 3/32". If so the joint is excessively worn and should be replaced.

Lower Ball Joint

1. With upper control arm support in position as shown in Fig. 2, disconnect lower ball stud from steering knuckle.
2. Assemble nut to lower ball stud and check rotating torque with a torque wrench. For new joints torque should be 4 to 8 ft. lbs. If torque readings are excessively high or low, replace ball joint.

Chevrolet

The upper joint is checked for wear by checking the torque required to rotate ball stud in the control arm.

1. Jack up under lower control arm at outer end and remove wheel.
2. Remove stud from steering knuckle.
3. Raise control arm to clear knuckle.
4. Install nut on stud and turn stud with torque wrench. This should be a minimum of 2 ft. lbs. If excessive wear is indicated, both upper and lower joints should be replaced. If a tight joint is suspected, 5 ft. lbs. is the maximum allowable torque with the joint well lubricated.
5. Reassemble and lower car to floor.

To check lower joint for wear, remove cotter pin and, with prick punch, mark nut and stud to identify relative location later. Tighten stud nut to original position with a torque wrench. If reading is less than 45 ft. lbs., stud may have been loose in steering knuckle and replacement of both lower joints is recommended.

CHEVY II FRONT END

Upper Ball Joint, Replace

1. With wheels on floor, install spacer support as shown in Fig. 2 between upper control arm and frame side rail. Then raise vehicle.
2. Remove wheel and tire.
3. Disconnect stabilizer link (if so equipped) and strut rod at lower control arm.
4. Remove nut from upper ball stud.
5. Strike upper part of steering knuckle with a hammer (backing up with another hammer). Drop lower control arm, steering knuckle and brake assembly with an adjustable jack until upper ball joint is easily accessible.
6. Chisel off three ball joint retaining rivet heads.
7. Attach replacement ball joint to control arm, using special bolts furnished with the replacement kit. Torque to 20-25 ft. lbs. *Do not attempt to use any bolts other than those in the kit as they are special hardened bolts.*
8. Raise lower control arm and steering knuckle in position. Insert upper ball stud into knuckle and torque stud nut to 42-47 ft. lbs.
9. Lubricate ball stud and complete the installation. Then check caster and camber.

Fig. 3 Chevy II front suspension

Lower Ball Joint, Replace

1. With vehicle weight on wheels, install spacer support, Fig. 2.
2. Raise vehicle and remove nut from lower ball stud.
3. Disconnect stabilizer at upper link. Strike lower steering knuckle boss and drop lower control arm until ball joint is easily accessible.
4. Cut off rivet heads and remove ball joint from lower control arm.
5. Install new ball joint, using the special hardened bolts furnished with the replacement kit. Torque to 20-25 ft. lbs.
6. Raise lower control arm and insert ball stud into steering knuckle. Install nut and torque to 42-47 ft. lbs.
7. Lubricate ball joint, and when assembly is completed, check caster and camber.

Riding Height

1. Position car on smooth, level floor.
2. Bounce front of car several times and allow it to settle to normal height, Fig. 3.
3. Measure distance from floor to centerline of lower control arm pivot.
4. Measure distance from floor to lower ball joint seat.
5. The difference of the distance between the measurements should be 2 to 3 inchs with vehicle at curb weight (full gas tank, spare tire and jack in trunk but no passengers).
6. Measure opposite side in same manner. Both sides must be within ½".
7. If riding height does not fall within these limits, the front springs should be replaced (do not shim springs).

Front Spring, Replace

1. Remove wheel and tire.
2. Support lower control arm with an adjustable jack and raise slightly from full rebound position.
3. Remove shock absorber.
4. With a suitable spring compressor, compress spring.
5. Remove lower spring seat retaining nuts and lift spring and seat from control arm and guide it down and out through fender skirt.
6. When installing new spring, *see that the spring coil ends are against spring stops in upper and lower seats. Locating tab on upper spring seat may be flattened before installing spring.*

Upper Control Arm

1. Remove spring and shock absorber.
2. Position adjustable jack under lower control arm.
3. Remove upper ball stud from knuckle.
4. Drop lower control arm and steering knuckle.
5. Unfasten upper control arm pivot shaft from fender skirt and remove control arm.
6. When installing control arm, torque pivot shaft nuts to 60-90 ft. lbs.

Lower Control Arm

1. With car weight on wheels, install spacer support, Fig. 2. Then raise car.

Fig. 4 Chevrolet 1955-62 ball joint front suspension

2. Loosen lower ball stud nut.
3. Loosen ball stud and remove nut. Then drop lower control arm.
4. Mark lower control arm pivot bolt and adjusting cam for realignment. Remove pivot bolt and cam assembly, Fig. 1. Remove lower control arm.
5. When installing, insert lower control arm into its support bracket. Index pivot bolt and cams, pivot nut and torque to 90-120 ft. lbs. Torque lower ball stud nut to 42-47 ft. lbs. Grease ball joint and lower vehicle. Then check and adjust caster and camber.

Shock Absorber

1. With car weight on floor, place support as shown in Fig. 2.
2. Raise car and remove wheel.
3. Disconnect lower shock absorber mounting nuts. Remove shock absorber upper mounting bracket bolts.
4. Lift bracket and shock absorber assembly from car.

FRONT END

1955-62 Corvette

Shock Absorber, Remove

1. With a ¼ in. open end wrench, hold the upper stem from turning and remove upper stem retaining nut, grommet retainer and grommet.

2. Remove nut and lockwasher from special bolt which retains lower bracket to control arm and pull the shock absorber and mounting bracket out through the lower control arm.

3. Place mounting bracket in a vise and remove the lower stem retaining nut, grommet retainer and grommet and remove shock absorber from bracket.

4. Inspect rubber grommets for condition and replace with new ones if necessary.

Shock Absorber, Install

1. Install grommet retainer, upper grommet, retainer bracket, lower grommet and retainer on bottom stem of shock absorber and install grommet retainer nut and tighten until it bottoms on shoulder of stem.

2. Install grommet retainer and grommet on upper stem of shock absorber and install shock absorber up through lower control arm and spring housing.

3. Index upper stud through mounting hole in top of spring housing and index hole in retainer bracket over special bolt in lower control arm.

4. Install lockwasher and nut on special bolt and tighten nut securely.

5. Install grommet and retainer over upper stem of shock absorber.

6. Install retainer nut to shock absorber upper stem, holding stem with a ¼ in. wrench. Tighten nut until it bottoms on shoulder of stem.

Front Spring, Remove

1. Disconnect stabilizer link from lower control arm.

2. Remove shock absorber as outlined previously.

3. Raise front end of car off floor and place stand jacks beneath frame side rails. Lower car until weight is carried on jacks.

4. Place an adjustable jack under the lower control arm inner shaft on side from which spring is to be removed.

5. Unfasten lower control arm inner shaft brackets from frame and drive out fastening bolts.

6. Lower jack slowly to relieve spring pressure and remove the jack. This allows the lower control arm to drop down, releasing the spring. If a shim is used, make sure it is removed from the upper spring seat.

Front Spring, Install

1. Install flat end of spring up with shim (if used) in place. Then raise lower control arm, making sure lower end of spring seats in recess in lower spring seat.

2. Place adjustable jack under lower control arm inner shaft. Slowly raise arm with jack to compress the spring. Use a long drift punch through the shaft bracket hole and hole in frame cross member to maintain alignment.

3. Install bolts through bracket and frame and tighten nuts securely.

4. Remove adjustable jack, raise car and remove stand jacks from under frame. Lower car to floor, connect stabilizer link, and install shock absorber.

Kingpins & Bushings, Install

When replacing the floating kingpin bushings, it is not necessary to ream them to size as service bushings are machined to finished dimensions. However, when replacing these bushings, care must be exercised to make sure the oil groove in the bushing lines up with the grease fitting in the steering knuckle. These bushings should be free both on the kingpin and in the steering knuckle.

1. Install new bushings in the steering knuckle and place the knuckle on the knuckle support. Then install the thrust bearing between the lower yoke of the steering knuckle and knuckle support, making sure that the shield on the bearing is toward the top.

Fig. 5 Installing spring compressor to hold spring slightly compressed while removing lower control arm. Chevrolet

2. Install the kingpin from the bottom, making sure to line up the lock pin slot with the lock pin hole in the knuckle support.

3. After the kingpin is installed, check the clearance between the steering knuckle and knuckle support with a feeler gauge. If this clearance is more than .006 in., install a steel shim between the knuckle and the top of the knuckle support.

4. Install the kingpin lock pin, bearing plugs, lock rings and bearing plug covers. Install the wheel and check the toe-in and adjust if necessary.

CHEVROLET FRONT END

Shock Absorber, Replace

Hold the shock absorber upper stem from turning with a suitable wrench and remove the nut and grommet. Unfasten the lower shock absorber pivot from the lower control arm and pull the shock absorber and mounting out at the bottom of the spring housing.

To install, reverse the removal procedure. Tighten the upper retaining nut until it bottoms on the shoulder of the stem. Torque the nut to 4-6 lb. ft. and stake in place.

Coil Spring, Replace

1. Remove shock absorber.
2. Jack up car and place stand jacks under frame side rails.
3. Remove wheel assembly to avoid damage to ball joints during spring operations.
4. Loosen 4 lower control arm cross shaft bushing bolts.
5. Install Special Spring Compressor or its equivalent through shock absorber mounting hole in front cross member and through spring. Install plate, thrust washer and nut and tighten so the spring is compressed slightly, Fig. 5.

6. Remove nut from lower ball joint. Loosen the stud by hammering on the side of the steering knuckle joint boss, backing up the knuckle with a heavy hammer.
7. Remove upper ball joint stud in similar manner, and hang drum and knuckle assembly so as not to place a strain on brake hose.
8. Unfasten lower control arm inner shaft from frame cross member.
9. Unscrew spring compressor nut and remove spring from vehicle.
10. Installation is made in the reverse order of removal with the aid of the spring compressor, Fig. 6. Rotate spring to be certain it fits the helical seats in both the cross member and lower control arm.

Lower Control Arm & Ball Joint

When replacing the lower control arm, ball joint, shaft or shaft bushings, it is necessary to remove the lower control arm from the vehicle.

The lower control arm ball joint should be replaced whenever excessive wear is indicated in the upper joint. The lower control arm ball joint stud is a loose fit in the assembly when not connected to the steering knuckle.

To replace the ball joint, chisel or drill rivet heads retaining the ball joint to the control arm and drive out the rivets. Discard the ball joint and seal. Install the new ball joint with flange against the under side of the control arm. Install and retain shield and joint in place with special bolts and nuts supplied with new joint. Tighten nuts to 10-12 lb. ft.

Upper Control Arm & Ball Joint

1. To remove, support vehicle weight at outer end of lower control arm.
2. Remove wheel assembly.
3. Remove nut from upper ball stud and loosen stud by hammering at side of steering knuckle joint boss, backing up knuckle with heavy hammer.
4. Unfasten upper control arm from cross member, *noting the number of shims at each bolt.*
5. Remove upper arm from car.

HORN SOUNDER & STEERING WHEEL

Chevy II

1. To remove, pry out horn button.
2. Remove three screws attaching receiver cup (or horn ring) and bushing spacer to steering wheel. Then remove flat belleville spring.
3. Remove nut and washer from steering shaft. Then use a suitable puller to remove steering wheel. *Do not lose the spring or seal located on the shaft under the steering wheel.*
4. Replace all components in the reverse order of removal. Make sure that the mark on the steering shaft lines up with the mark on the steering wheel hub. Torque wheel retaining nut to 35-40 ft. lbs.

Chevrolet & Corvette

On 1958-62 models, remove two screws from back of steering wheel and remove ornamental cap and horn sounding mechanism.

Fig. 6 Installation of spring and lower control arm with the aid of spring compressor. Chevrolet

On 1955-57 models, pry off horn button or ornamental cap and remove horn control mechanism.

After removing horn sounding mechanism as outlined above, remove steering wheel nut and use a puller to remove steering wheel.

CHEVY II STEERING GEAR

Adjustments

1. Disconnect pitman arm from steering rod.
2. Loosen steering gear housing attaching bolts at underbody side rail to relieve possible binding between steering column and worm shaft.
3. Loosen steering column bracket screws at instrument panel.
4. Partially tighten steering column bracket screws.
5. Torque steering gear housing attaching bolts to 25-35 ft. lbs.
6. Loosen sector shaft adjusting screw lock nut and turn screw counterclockwise.
7. Measure worm bearing preload by hooking a spring scale to steering wheel rim. Read pull required to keep wheel moving for at least one complete turn. If spring scale pull is not within the limits ½ to ⅞ lbs., adjust as follows:
8. Loosen steering shaft bearing adjuster lock nut and tighten or back off bearing adjuster, Fig. 7, to bring preload within specified limits.
9. Tighten steering shaft bearing adjuster lock nut and recheck preload.
10. Turn steering wheel slowly to each stop. *Turn gently against stops to avoid damage to ball return guides.* Then rotate wheel halfway back to center ball nut.
11. Turn sector adjusting screw clockwise until ½ to 1¼ lbs. on spring scale is necessary to rotate worm past center. *No perceptible backlash is permissible at 30° on either side of center—1 and 11 o'clock positions.*
12. Tighten sector adjusting screw lock nut and recheck backlash adjustment.
13. Tighten steering column bracket bolts and connect sector shaft arm to steering rod.

Steering Gear, Replace

1. If car is equipped with power brake cylinder and/or clutch push rod,

Fig. 7 Chevy II steering gear

these must be removed.
2. Remove pitman arm retaining nut. Mark position of pitman arm on sector shaft with a punch.
3. Remove pitman arm from sector shaft.
4. Remove mast jacket.
5. Unfasten steering gear from its mounting and remove from car.

Steering Gear Repairs

1. Rotate steering worm until nut is in center of travel, Fig. 7.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined previously.

CHEVROLET & CORVETTE STEERING GEAR

Replace, 1955-57

1. Disconnect all electrical connections.
2. Remove back-up light switch (if equipped) from mast jacket.
3. Remove two rubber cover upper fasteners from inside of dash panel at mast jacket opening to permit clearance for shift levers during removal.
4. Pry off horn button or ornamental cap and remove horn mechanism.
5. Remove steering wheel.
6. Remove retaining nut, washers and bolt from dash panel attaching bracket. *Do not remove the two lower retaining bolts from dash panel attaching bracket or realignment of mast jacket-to-steering gear shaft will be necessary.*
7. Disconnect transmission control linkage from shifter levers on steering column.
8. Slide rubber seal away from covers, unfasten and remove covers.
9. Unfasten mast jacket clamp from instrument panel and remove clamp and shims.
10. On Powerglide models, disconnect indicator rod from lever, then remove transmission control selector plate.
11. Pull assembly up off steering gear shaft.
12. Disconnect pitman arm from shaft.
13. Unfasten steering gear from frame and remove gear.
14. Remove four felt seals from mainshaft of steering gear.
15. Reverse the above procedure to install the gear.

Replace, 1958

The new forward position of the steering gear introduces a universal coupling into the steering shaft assembly. This coupling is packed with special grease at the factory and should not be disassembled unless absolutely necessary.

It is not necessary to remove the coupling to remove the steering gear. Simply remove the lower clamp bolt and disconnect the steering gear from the pitman arm and frame. The lower shaft and steering gear can then be pulled from the coupling.

If binding is felt after the gear is installed, the difficulty is probably due to misalignment of the shafts. Misalignment is corrected as follows:

To correct vertical misalignment, loosen the three steering gear housing bolts. The front bolt holes in the frame are elongated to permit pivoting around the rear bolt. Pivot steering gear as required and tighten bolts.

To correct lateral misalignment, add or remove shims between the rear steering gear mounting bolt and the frame. Each $\frac{1}{32}$" shim will move the upper end of the lower shaft in or about ¼". *Standard shimming is two shims at the pivot bolt. If four shims do not correct misalignment, the lower steering shaft may be bent. Likewise, if removing all shims does not correct misalignment, the shaft may be bent.*

Coupling, Replace

1. If necessary to remove the coupling, first mark both shafts at "12 o'clock" position.
2. Remove snap ring.
3. Remove bolt from upper shaft clamp so coupling cover can be raised without interference.
4. Remove upper and lower mast jacket clamp bolts.
5. Pull steering wheel and mast jacket to rear as far as possible.
6. Raise cover and remove both bearing blocks from pin.
7. Support lower end of upper shaft and drive out pin with brass drift.
8. Remove coupling lower clamp bolt.
9. Raise coupling off serrations on lower steering shaft and remove. If necessary, shift mast jacket to one side to obtain clearance for removal.
10. Remove coupling cover and upper seal.
11. Inspect the coupling parts for damage, including the O-ring seal and upper seal.
12. Assemble the coupling, following the reverse of the removal procedure. Be sure the coupling pin is centered so the cover will slide freely over the coupling blocks. Then, before lowering the cover, pack the coupling with chassis lubricant. Lower the cover, being careful not to damage O-ring seal. Install snap ring.

Replace 1959-62

This steering gear is similar to that used in 1958 except that a second coupling has been added which will facilitate alignment of the steering gear housing. The housing is no longer shimmed for adjustment or has it got slotted holes for rotational adjustment.

To remove the lower coupling with all steering gear components in the vehicle either the steering gear has to be removed or lowered from its proper location and the upper coupling loosened, or the mast jacket, upper steering gear shaft and coupling must be loosened and pulled upward far enough to allow removal of the intermediate shaft and lower coupling.

However, if the upper steering shaft, mast jacket and upper coupling has been removed, the lower coupling may be removed as follows:

1. Remove special bolt from coupling clamp.
2. Tap coupling upward with a soft mallet to remove. The coupling is a splined part of the intermediate shaft.
3. If the coupling is to be disassembled, first scribe marks across the mating parts for proper reassembly, then separate coupling.
4. Reverse removal procedure to assemble and install the coupling and torque the special bolt into the clamp to 14-20 lb. ft.

Steering Gear Repairs

1. Rotate steering worm until nut is in center of travel, Fig. 8.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm

Fig. 8 Chevrolet and Corvette steering gear disassembled

and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined below:

Adjustments

1. Disconnect steering relay rod from pitman arm.
2. Loosen sector shaft lash adjuster screw a few turns to relieve load from bearings.
3. Turn steering wheel in one direction until stopped by gear, then back away about one turn.
4. With a spring scale hooked to rim of steering wheel, measure pull required to keep wheel in motion; this should be ⅜ to ⅝ lb. If not within these limits, adjust worm bearings as follows:
5. Loosen worm bearing adjuster lock nut and turn adjuster until there is no perceptible end play in worm. Check pull at wheel rim, readjusting as required to obtain proper pull. Tighten lock nut and recheck pull.
6. After worm bearing adjustment is completed and all mounting bolts tightened, adjust sector shaft end play.
7. With steering wheel in straight-ahead position, turn lash adjuster screw clockwise to remove all lash and tighten lock nut.
8. Check pull at rim of steering wheel, taking highest reading on scale as wheel is turned through the central or straight-ahead position. This should be between ⅞ and 1½ lbs. *If more than 1½ lb., turn lash adjuster screw counterclockwise, then come up on the adjustment in a clockwise motion.*
9. Tighten lock nut and recheck pull.

Service Note

Due to the off-center location of the steering shaft in relation to the mast jacket, it may be necessary to adjust for concentricity as follows: With shift levers in neutral, slip the cover and spring on the steering shaft below adjusting ring towards steering gear box. Install the tool shown in Fig. 9 between the steering shaft and adjusting ring. Holding the tool at a point of contact bisecting keyway in adjusting ring as shown, insert a $\frac{5}{64}$" drill or welding rod between steering shaft and tool. If shaft is not properly located, loosen upper dash panel bracket bolt and the two lower bracket retaining bolts. Exert slight pressure against $\frac{5}{64}$" rod and the tool and tighten first the upper bolt and then the two lower bolts.

POWER STEERING UNIT, REPLACE

1. To remove the unit from the car, take out the horn button or ornamental cap and unscrew the steering wheel retaining nut.
2. Remove steering wheel with a suitable puller.
3. Remove upper control shaft clamp bolt from shaft connector.
4. Disconnect horn wire at connector under the instrument panel near where the horn wire comes from the mast jacket.
5. Remove steering mast jacket toe board grommet and seal from toe board.
6. Remove mast jacket clamp from instrument panel.
7. Remove two screws that attach gearshift control upper support to mast jacket. The upper control shaft and support may now be pulled up and out of engagement from shaft connector.
8. Remove clamp bolt nuts and clamp

Fig. 9 Checking for concentricity of steering shaft location in mast jacket. Chevrolet.

retaining the shifter housing to the mast jacket. Then rotate shifter housing, with lower control shaft and control rods attached, away from mast jacket.

9. Disconnect steering connecting rod at pitman arm, *taking care to note relative position of steering connecting rod parts before disturbing them.*
10. Disconnect steering pump-to-valve body hoses at valve body unit. *Secure the end of hoses in a raised position to prevent drainage of oil.*
11. Unfasten steering gear housing from steering support bracket.
12. Remove left air duct.
13. Rotate gear assembly to clear fender skirt and raise steering gear assembly, bringing it up and forward to remove from engine compartment.
14. Reverse the foregoing procedure to install the gear assembly. Tighten steering gear housing-to-steering support bracket bolts to 27-40 lbs. ft. torque. Also tighten steering wheel retaining nut to 35-40 lbs. ft. torque.

POWER STEERING REPAIRS, 1955-62

Power steering equipment consists of a recirculating ball type steering gear and linkage to which a hydraulic power mechanism has been added as part of the steering linkage. The hydraulic mechanism furnishes additional power to *assist* the manual operation so that the turning effort at the steering wheel is greatly reduced. The hydraulic mechanism consists of three basic units: a hydraulic pump and reservoir, a control valve, and a power cylinder.

PUMP REPAIRS

Removal, Fig. 10

1. On 6-cyl. cars only, remove fan belt and pull generator away from engine.
2. Disconnect hydraulic lines from pump, allowing fluid to drain from reservoir into a container.
3. Unfasten and remove pump.

Disassemble

1. Drain remaining fluid from reservoir.
2. Remove reservoir from pump.
3. Remove pump cover and filter.
4. Disassemble pump.

Inspection

1. Wash and dry all parts.
2. Inspect fit of vanes in rotor. Vanes must slide freely but snugly in slots. Tightness may be relieved by removal of irregularities.
3. Inspect flat faces of pressure plate, cam ring, pump cover, rotor and pump body. These faces may be repaired by lapping until smooth and flat. Remove all lapping compound.
4. Inspect cylindrical surface of pressure relief control valve and check fit of this valve in pump body. Slight irregularities may be corrected by polishing.

Fig. 10 Power steering pump

Assemble, Fig. 10

1. Lubriplate and install new O-rings in pump cover, on cam ring and in pump body.
2. Install rotor and vanes on pump body with wear patterns or beveled edge of vanes against cam ring inner diameter.
3. Install alignment sleeve in cam ring and install cam ring in pump body. *The wider edge of cam ring is correct side to pump body. Be certain to align bolt holes in cam ring and pump body. Rotor should be installed with rounded side of splines toward generator end of pump.*
4. Install pressure plate in cover.
5. Install filter and retainer.
6. Install cover to pump body.
7. Install plunger and flow spring in pump cover.
8. Install filter retainer spring in cover.
9. Install reservoir, two bolts and two sealing washers. *The brass fitting seats are the pressed-in type and are replaceable in the event of a fitting leak by tapping threads in the hole of the seat and then pulling the seat by using a bolt threaded into the tapped out seat and a flat washer and nut as an extractor.*
10. When installing new seats, align seat in its bore and press it into place, using the correct hose or tube fitting as a pressing tool.
11. Install pump on car and fill and bleed system as outlined further on.

CONTROL VALVE REPAIRS

Removal, Fig. 11

1. Loosen relay rod-to-control valve clamp.
2. Disconnect hose connections at control valve.
3. Disconnect control valve from pitman arm.
4. Unscrew control valve from relay rod.
5. Remove control valve from car.

Disassemble

1. Remove dust shield from valve housing.

Fig. 11 Power steering control valve

2. Remove retaining pin and nut from valve shaft.
3. Separate valve housing from adapter housing.
4. Remove parts from valve shaft.
5. Remove ball stud cover from adapter housing.
6. Pull ball stud to end of adapter housing and remove lock pin.
7. Remove ball plug adjuster and valve shaft.
8. Remove ball seat plug and spring.
9. Remove seats and ball stud.
10. Remove bearing sleeve.

Inspection

1. Wash and dry all metal parts.
2. Inspect all parts for scratches, burrs, distortion, evidence of wear and replace all worn or damaged parts, including mating parts where necessary.
3. Replace all seals, gaskets and covers.

Assemble

1. Place ball seat in bearing sleeve and insert sleeve in housing.
2. Insert ball stud in sleeve.
3. Install other ball seat, spring and spring seat in sleeve.
4. Install valve shaft in adjuster and screw adjuster into bearing sleeve. *Adjuster should be tightened until it bottoms, and should then be backed off ¼ turn plus or minus amount necessary to insert lock pin in nearest hole.* Be sure ball ends remain in correct position, otherwise there will be insufficient clearance to correctly install retaining pin.
5. Install ball stud cover.
6. Install washer and spacer on valve shaft.
7. Install Vee seal block and ring.
8. Install annulus washer, spring and spring thrust washer with chamfered side of thrust washer toward spool side.
9. Install spool valve and retaining nut. *Spool valve is installed with Vee seal at threaded end of valve shaft.*
10. Tighten retaining nut to a torque of 25 inch lbs. and install retaining clip.
11. Insert assembled valve and adapter into valve housing and install two retaining bolts and lockwashers.
12. Fill end area with approved grease and install dust cover.

Installation

1. Install control valve on relay rod so that the distance from the center of the control valve ball stud to the center of the tie rod is approximately 3⅝".
2. Tighten control valve clamp. *Clamp should be positioned before tightening so that it will not interfere with the steering linkage.*
3. Connect four hydraulic hoses to control valve.
4. Fill reservoir and bleed system as outlined further on.

Adjust, 1960-62

1. Disconnect cylinder rod from frame bracket.
2. With car on a hoist, start the engine. One of the following two conditions will exist:
   a. If piston rod remains retracted, turn the adjusting nut clockwise until the rod begins to move out. Then turn the nut counterclockwise until the rod just begins to move in. Now turn the nut clockwise to exactly one half the rotation needed to change the direction of shaft movement.
   b. If the rod extends upon starting the pump, move the nut counterclockwise until the rod begins to retract, then clockwise until the rod begins to move out again. Now turn the rod to exactly one half the rotation needed to change the direction of shaft movement. *Do not turn the nut back and forth more than is absolutely necessary to balance the valve.*
3. Restart engine. Front wheels should not turn from center if valve has been properly balanced.

POWER CYLINDER REPAIRS

Removal

1. Disconnect two hydraulic lines at power cylinder.
2. Unfasten power cylinder rod from brace at frame.
3. Unfasten power cylinder from relay rod bracket.
4. Remove power cylinder from car.

Inspection

1. Inspect seals for leaks around cylinder rod and if leaks are present, replace seals as follows:
2. Use a hook tool to remove retaining ring. Remove wiper ring, back-up washer, back-up ring and seal. *Piston rod seal should not be removed unless there are signs of leakage along the piston shaft at shaft seal.*
3. Examine brass fitting hose connection seats for cracks or damage and replace if necessary.
4. For service other than seat or seal replacement, replace the power cylinder.

Installation

1. Install power cylinder on car by reversing removal procedure.
2. Reconnect two hoses, fill system with fluid and bleed system as outlined below.

Filling & Bleeding System

1. Fill reservoir to proper level with Automatic Transmission Fluid and let fluid remain undisturbed for about two minutes.
2. Raise front wheels off floor.
3. Run engine at idle for two minutes.
4. Increase engine speed to about 1500 rpm.
5. Turn wheels from one extreme to the other, lightly contacting stops.
6. Lower wheels to floor and turn wheels right and left.
7. Recheck for leaks.
8. Check oil level and refill as required.

Instruments and Windshield Wiper

INSTRUMENT CLUSTER

Chevy II

1. Loosen and lower mast jacket from dash panel.
2. Unscrew retaining collar securing speedometer cable to speedometer head.
3. Unfasten cluster from dash panel (4 screws). Cluster may now be pulled clear of dash. *Do not pull cluster outward further than slack in wiring harness will allow, otherwise harness retaining clips may be damaged.*
4. Remove two harness retaining clips from rear of cluster. Cluster may now be positioned face down on mast jacket for removal of fuel gauge.
5. Disconnect all bulb sockets, carefully noting their location for proper installation. Remove cluster from car.

1955-56

In order to remove the speedometer, first detach and pull the instrument cluster assembly from the instrument panel opening.

1957

The instrument cluster must be removed in order to remove the speedometer. On cars with automatic transmission, first disconnect the indicator rod from the lever before removing the instrument cluster.

1958

Detach and pull the instrument cluster from the instrument panel opening. Also remove all instrument lamps and high beam indicator lamp from back of speedometer. Then remove speedometer.

1959-60

1. Remove five lamp sockets and speedometer cable from back of speed-

ometer unit.
2. From under dash, remove nut from stud at top of instrument cluster.
3. On passenger side of instrument panel, remove two screws securing bottom of housing to dash.
4. Remove speedometer head from housing by removing three screws.

1961-62 Chevrolet

To remove the instrument cluster or console, two clamps must be loosened and slid up the mast jacket. The upper clamp connects the mast jacket to the instrument panel support and the lower clamp connects the lower end of the mast jacket to the firewall support.

The steering wheel and mast jacket assembly can now be lowered to provide the necessary clearance for removing the instrument console. Six screws around the console hold it in place and permit quick removal so all instruments are accessible for maintenance or installation.

WINDSHIELD WIPER

Chevy II

1. Make certain wiper motor is in park position.
2. Remove special clip retaining transmission linkage to motor crank arm. Then remove linkage, electrical connectors and washer hoses (if equipped).
3. Unfasten and remove motor (3 screws).
4. Install in reverse order of removal. Check and replace motor gasket if necessary. Use sealing compound in screw holes.

1955-57

The wiper transmission cables are tensioned by spring loaded pulleys. The end of the transmission shaft is pushed in to unlock the pulleys. To tension the cables, push in on the transmission shaft end if blade has been removed or on the base of the wiper arm if the blade is installed.

To release cable tension for removal of component parts, push in on the transmission shaft and have a helper on the inside of the car pull on the cables to obtain the desired slack. Then release pressure on transmission shaft. *Wiper blade snap or over-travel indicates loose transmission drive cables.*

To remove the wiper motor, proceed as follows:

1. Remove the glove compartment box.
2. Adjust cables to slack position and detach them.
3. Unfasten motor from drive assembly and remove. Drive assembly can now be removed from dash panel.

1958-61

1. Make certain motor is in parked position.
2. Remove cowl vent grille from car.
3. Remove washer nozzles and disengage drive linkages from motor.
4. Under the instrument panel, disconnect electrical connector or control cable and vacuum line from wiper motor.
5. Remove retaining screws and pull motor out and down to remove.

1962 Chevrolet

1. Make certain motor is in parked position.
2. Remove plenum chamber ventilator grille. Remove windshield washer nozzles (if used).
3. Remove ground strap retainer screw, washer hoses if present, all electrical connectors and wiper transmission drive arm to motor crank arm retainer clip. *Mark washer hoses for correct installation.*
4. Unfasten and remove motor.
5. When installed, check wiper operation before installing chamber ventilating grille. Make sure motor is properly grounded.

①—Fit rings in tapered bores for the clearance listed in tightest portion of ring travel.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

①—For each 10° rise in temperature subtract .04 volt; for each 10° drop add .04 volt. Temperature is checked with a thermometer 2 inches from installed voltage regulator cover.
②—Current draw at 12 volts while turning rotor shaft by hand. ③—Plus or minus 3 amperes. If output is low, stator or rectifier is shorted.

GENERATOR AND REGULATOR SPECIFICATIONS

★To polarize generator, reconnect the leads to the regulator; then momentarily connect a jumper wire from the "Arm" to the "Bat" terminals of the regulator.

Engine Section

ENGINE MARKINGS

The letter "A" immediately following the engine number indicates .020″ oversize cylinder bores.

The letter "B" immediately following the engine number indicates .010″ undersize crankshaft journals.

The letters "AB" immediately following the engine number indicates .020″ oversize cylinder bores and .010″ undersize crankshaft journals.

A maltese cross ⅜″ high stamped on the engine numbering pad indicates a crankshaft that has one or more connecting rods and main bearings finished .001″ undersize.

A diamond shaped mark stamped on the engine numbering pad indicates that all valve lifter bodies are .008″ oversize.

ENGINE, REPLACE

In addition to the usual items such as fuel lines, linkage, propeller shaft, etc., it is necessary to perform the following operations:

1. Remove hood and battery.
2. Remove radiator and exhaust pipes.
3. On 1953-55 models, support transmission and remove engine rear support and crossmember. Remove front support bolts and lift engine out toward the left front fender.
4. On 1956-59 models, support transmission and remove engine rear crossmember. Remove front supports and lift engine and transmission out of chassis.
5. On 1960-61 models, remove number 6 spark plug. Then support rear of engine and remove the rear support crossmember and transmission. Remove engine front mounting and lift engine from chassis.

CYLINDER HEAD

Chrysler, De Soto, Imperial 1959-62

1. Drain cooling system.
2. Remove generator, carburetor air cleaner and fuel line.
3. Disconnect accelerator linkage.
4. Remove vacuum control tube at carburetor and distributor.
5. Disconnect heat indicator sending unit wire.
6. Remove spark plugs located under manifolds.
7. Remove intake manifold, ignition coil and carburetor as a unit.
8. Remove valve lifter chamber cover.
9. Remove rocker arm covers. *On air conditioned cars, No. 8 cylinder exhaust valve must be open to allow clearance between right-bank cylinder head cover and heater housing.*
10. Remove exhaust manifolds.
11. Remove rocker arm assemblies.
12. Remove push rods.
13. Remove head attaching bolts and take off heads.
14. Installing the heads is a matter of reversing the removal procedure. Tighten attaching bolts in the sequence shown in Fig. 1.

1955-58

1. Drain cooling system.
2. Remove generator, carburetor air

cleaner and fuel line.
3. Disconnect accelerator linkage.
4. Remove vacuum control tube at carburetor and distributor.
5. Disconnect coil wires and heater hose.
6. Remove heat indicator sending unit wire.
7. Remove oil level dipstick.
8. Remove air tube between automatic choke and exhaust manifold.
9. On 1955-56 models, remove bolts attaching water pump housing to cylinder heads and loosen remaining water pump housing bolts to allow sufficient forward movement to facilitate installation of cylinder head-to-water pump gaskets.
10. On 1957-58 models, remove water outlet manifold and heater blower.
11. Remove ignition cable cover, spark plugs and tubes.
12. Remove intake manifold, ignition coil and carburetor as an assembly.
13. Disconnect exhaust pipes at manifold flanges.
14. Remove rocker arm assemblies.
15. Remove push rods, keeping them in proper order so each will be reinstalled in its original location.
16. Lift off cylinder head.
17. Reverse foregoing procedure to install head or heads and tighten in the sequence shown in Fig. 2.

ROCKER ARMS

Chrysler & Imperial 1959-62 & De Soto 1958-61

Disassemble the rocker assemblies by removing the bolts from the support brackets. Then slide brackets, rocker arms and spacers from the shaft, Fig. 4.

Clean all parts except the oilite spacers in a suitable solvent. Keep oilite spacers soaked in engine oil until reassembled. Inspect all parts for excessive wear. Test shaft end plugs for any evidence of leaks.

Install the rocker shafts so the oil holes are positioned as shown in Fig. 5. *It is important that the shafts be installed as indicated, otherwise excessive oil spray and improper lubrication of the valve mechanisms can result.*

Assemble rocker arms in pairs between brackets with an oilite spacer between the arms. The push rod ends of all rocker arms must face in the same direction as the arrow on the shaft. Install bolts through the brackets to hold assembly together.

Chrysler & Imperial 1955-58 & De Soto 1955-57

Sludge and gum formation in the rocker arms and shafts, Figs. 6 and 7, will restrict the normal flow to the rocker arms and valves. Each time the assemblies are removed, they should be disassembled and thoroughly cleaned.

Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Inspect the shafts for wear. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When the assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves.

Check each push rod for a bent or damaged condition. If bent more than .020", when checked with an indicator, replace the push rod. Do not attempt to straighten a bent rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

Fig. 4 Rocker arm assembly. 1959-62 Chrysler and Imperial and 1958-61 De Soto

VALVES, REMOVE

With cylinder head removed as outlined previously, use a suitable valve spring compressor to compress the spring in order to take out the valve locks. Then remove spring retainers, valve stem cup seal or seals and valve springs. Remove burrs from valve stem lock grooves to prevent damage to valve guides and slide valves from heads.

Fig. 6 Rocker arm assembly. 1953-58 Chrysler and 1953-57 De Soto single rocker shaft engines

Fig. 8 Checking installed height of valve springs. Double rocker shaft engines

Place the valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to the original guide holes.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Figs. 8 and 9. If the assembled height is greater than the dimension given in the *Valve Specifications Chart*, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is $\frac{1}{16}$", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

Fig. 7 Top and bottom view of double rocker shaft assembly

VALVE SPRING TESTING

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available, Fig. 10. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Data* chart within 10 per cent should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES

Double Rocker Shaft Engines

If necessary, remove the old guides by driving them out through the top of the cylinder head. Drive the new guides in place up through the valve port opening to the position shown in Figs. 11 and 12.

Single Rocker Shaft Engines

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of three service valves with oversize stems (.005", .015" and .030").

After cleaning the valve guide holes, check the clearance as follows:

Install a suitable sleeve over the valve stem to keep the valve at working height for easy checking with a dial indicator, Fig. 13. Attach the dial indicator to the head and set it at right angle to edge of valve being checked. Move the valve to and from indicator. The total indicator movement should not exceed .010" on intake valves, or .014" on exhaust valves.

Fig. 9 Checking valve spring installed height. Single rocker shaft engines

If readings exceed the above tolerances, ream the guide holes and install valves with oversize stems. Always use a .005″ reamer first and, if necessary, a .015″ then a .030″ reamer so the valve guides may be reamed true in relation to the valve seat.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

If refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$″, otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face, Fig. 14.

Inspect the valve seats in the block for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

The valve seat width after refacing should be a liberal $\frac{1}{16}$″ for intake seats but not more than $\frac{3}{32}$″ in any case. The width of exhaust seats should be $\frac{3}{64}$″ to a liberal $\frac{1}{16}$″.

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.*

After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the tests to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

HYDRAULIC LIFTERS

Figs. 15 and 16 illustrate the types of hydraulic valve lifters used. See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Place one end of the hose near each valve in progression and listen through the other end. In this manner the sound is local-

Fig. 10 Fixture and torque wrench for checking valve spring pressure

Fig 13 Checking valve guide clearance

Fig. 11 Valve guide details. De Soto engines with double rocker shafts

Fig. 12 Valve guide details. 1955 Chrysler and Imperial double rocker shaft engines. For 1956-58 exhaust guide measurement is 1 3/64″

ized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

Lifter, Replace

Chrysler Tool C-3158 is available for this operation. To remove the lifter, insert the hooked portion of the tool in the lifter body. (This portion of the tool can be used to remove lifters without a varnish build-up around the bottom of the body.) Lift the lifter out of the bore. If they are stuck, proceed as follows:

Slide the puller portion of the tool through the cylinder head push rod holes and seat it firmly in the top of the lifter. Insert the puller pin through the body and tool shaft in the holes provided, Fig. 17. Grasp the tool handle and pull the lifter out of the bore as shown. As the lifter clears the bore, withdraw the puller pin and remove the tool.

Service Note

Hydraulic plungers and bodies are not interchangeable. Therefore, it is advisable to work on one lifter at a time to avoid mixing parts. *Mixed parts will not function.* Moreover, do not mix check valves as they may be slightly worn and will fit only the plungers with which they have been operating.

When installing hydraulic lifters in the engine, fill them with light engine oil (10W) to avoid excessive time required to quiet them during initial operation of the engine.

CHAIN CASE COVER

1955

1. Remove radiator, fan, fan shroud and water pump housing.
2. Remove pulley and damper from hub and, with a puller, remove hub.
3. Loosen oil pan bolts and drop pan slightly to clear chain case cover.

Fig. 14 Valve nomenclature

Fig. 15 Hydraulic valve lifter. 1956-62

4. Remove fuel pump.
5. Unfasten and remove chain cover.

1956-58 Chrysler & Imperial & 1956-57 De Soto

1. Remove radiator and water pump.
2. Use a puller to remove vibration damper.
3. Remove chain cover and gasket.

1959-62 Chrysler & Imperial & 1958-61 De Soto

1. Drain cooling system.
2. Remove radiator, fan and belt.
3. Remove water pump and housing as an assembly.
4. Remove crankshaft bolt and two pulley bolts and use a puller to remove vibration damper.
5. Remove chain case cover and gasket, using extreme caution to avoid damaging oil pan gasket.
6. Remove key from crankshaft.

TIMING CHAIN

1955

After removing the chain case cover as outlined previously, remove the camshaft sprocket hub nut, fuel pump eccentric and dowel assembly. The camshaft sprocket and timing chain may now be taken off.

To install, rotate the crankshaft until the zero mark on the crankshaft sprocket is exactly in line with the center of the camshaft. Temporarily install the camshaft sprocket (less chain) and line up the hub dowel pin hole with the sprocket dowel pin hole, while at the same time positioning the camshaft sprocket zero mark exactly in line with the center of the crankshaft. A straight edge should be used to check the accuracy of this alignment, Fig. 19..

Remove the camshaft sprocket again and position it in the timing chain. Then place the chain on the crankshaft sprocket. Install the camshaft sprocket, being sure both zero timing marks are facing each other and in line with the center of both the camshaft and crankshaft.

1956-62

To install chain and sprockets, lay both the camshaft and crankshaft sprockets on the bench. Position the sprockets so that the timing marks are next to each other. Place the chain on both sprockets, then push the gears apart as far as the chain will permit. Use a straightedge to form a line through the exact centers of both gears. The timing marks must be on this line, Fig. 19.

Slide the chain with both sprockets on the camshaft and crankshaft at the same time; then recheck the alignment.

Install the fuel pump eccentric on the camshaft and install cup washer and bolt. Tighten bolt to a torque of 35 lb. ft.

CAMSHAFT, REPLACE

1955

To remove the camshaft, remove the valve lifter cover, then proceed as follows:

1. Remove cylinder head covers and push rods.
2. Remove valve lifters, arranging them in a board with numbered holes so they may be reinstalled in their original bores.
3. Remove ignition distributor.
4. Remove chain case cover, chain and camshaft sprocket.
5. Remove camshaft thrust plate screws.
6. Remove distributor and oil pump drive gear (tool C-3021 is available for this operation).
7. Pull out the camshaft, using care not to damage the camshaft bearings with the cam lobes.
8. Remove camshaft hub and thrust plate.
9. If camshaft bearings are to be replaced at this time, it is recommended that the engine be removed and the crankshaft taken out in order that any chips or foreign material may be removed from the oil passages.

1956-58 Chrysler & Imperial & 1956-57 De Soto

To remove the camshaft, remove intake manifold, valve chamber cover, push rods, valve lifters, timing chain and sprockets. Lift out distributor drive gear and shaft. Remove camshaft thrust plate attaching bolts and oil trough.

Fig. 16 Hydraulic valve lifter. 1955

Fig. 17 Removing stuck hydraulic valve lifter

Withdraw camshaft and spacer, being careful not to damage the camshaft bearings with the cam lobes.

1959-62 Chrysler & Imperial & 1958-61 De Soto

1. To remove camshaft, remove valve lifters, timing chain and sprockets.
2. Remove distributor and oil pump drive gear.
3. Remove fuel pump to allow push rod to drop away from cam eccentric.
4. Remove camshaft, being careful not to damage camshaft bearings.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

When installing piston and rod assemblies in the cylinders, the compression ring gaps should be diametrically opposite one another and not in line with the oil ring gap. The oil ring expander gap should be toward the outside of the "V" of the engine. The oil ring gap should be turned toward the inside of the engine "V".

Immerse the piston head and rings in clean engine oil and, with a suitable piston ring compressor, insert the piston and rod assembly into the bore. Tap the piston down into the bore, using the handle of a hammer.

Assemble the pistons to the rods as shown in Fig. 20.

PISTONS

Due to the necessity of maintaining piston balance, all pistons are machined to the same weight in grams, regardless of oversize. Only finished pistons are available in service and are supplied in standard and the following oversizes: .010, .020, .030, .040, .050, .060 inch.

Starting with the No. 1 cylinder, coat the bore very lightly with a light engine oil (10W). Insert the piston in the bore upside down with the feeler stock between the thrust face of the piston and cylinder wall.

While holding the piston, draw the feeler stock out straight with a spring scale attached to it. The amount of pull to withdraw the feeler stock should be as given in the charts. Fit the remaining pistons in like manner.

PISTON PINS

1959-62 Chrysler & Imperial & 1958-61 De Soto

With pistons and pins at room temperature (70°F.) the pin should be a sliding fit in the piston. The pin should be pressed into the connecting rod. Replacement is necessary if any free play exists between the pin and piston. Piston pins are available through Chrysler only with new pistons.

Fig. 19 Timing marks aligned for correct valve timing

Fig 20 Piston and rod assembly

1955-58 Chrysler & Imperial & 1953-57 De Soto

Piston pins are supplied in standard size and oversizes of .003" and .008". The fit of the pin in both the connecting rod and piston should be a tight thumb press fit with the parts at normal room temperature.

When using an expansion reamer to fit piston pins, start off by taking a very light cut. Try the fit. Then ream and try the fit again until the pin can be pushed into the rod and piston as described above.

PISTON RINGS

When new rings are to be installed without reboring cylinders, the glazed cylinder wall should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is fitted. An inverted piston can be used to push the rings down to this position. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If the feeler gauge is inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance may result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will inter-

Fig. 21 Checking bearing clearance by measuring width of flattened Plastigage

fere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the piston and rod assemblies merely by taking off the rod cap and replacing the upper and lower bearing halves.

The clearance between the bearings and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the bearing, Fig. 21.
3. Reinstall the bearing cap and tighten the bolts to the torque value given in the *Engine Torque Data* table.
4. Remove the bearing cap again and check the bearing clearance by measuring the width of the flattened Plastigage, Fig. 30. The measuring strip is supplied in the same envelope which contains the Plastigage.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out, Fig. 22.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque Data* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN

1955-56 V8 Chrysler, De Soto & Imperial

After disconnecting the steering linkage at the idler arm support bracket, allow the linkage to settle away from the oil pan. Remove necessary exhaust pipes. Then unfasten and remove the oil pan.

1957 De Soto

1. Drain oil and remove dipstick.
2. On single exhaust jobs, remove starting motor, disconnect exhaust pipes at the manifolds and at clamp to exhaust extension and move pipes out of the way. Be sure rest of exhaust system is properly supported.
3. Disconnect tie rod at idler arm and pull downward and out of the way.
4. There will be interference by the crankshaft during oil pan removal. Lower the oil pan and turn the crankshaft until No. 1 crankpin is at the 8 o'clock position and lower pan.

Fig. 22 Using special tool (1) in oil hole to turn upper main bearing in place

1957-58 Chrysler & Imperial

1. Drain oil and remove dipstick.
2. On cars with single exhaust, disconnect crossover and "Y" pipe at exhaust manifolds and at clamp to exhaust extension so that crossover and "Y" pipe may be moved out of the way. Be sure rest of exhaust system is properly supported.
3. Remove converter dust shield.
4. Remove starting motor.
5. Remove nuts from front engine mounts and raise engine about ¾ inch.
6. Rotate crankshaft so as to bring the ignition timing mark 180 degrees from the timing pointer.
7. Disconnect steering linkage at idler arm support bracket and allow linkage to settle away from bottom of oil pan.
8. Unfasten and remove pan.

1958 De Soto

1. Remove dipstick and drain oil.
2. Disconnect steering linkage from steering arm and pull linkage down and away from oil pan.
3. On single exhaust jobs, remove exhaust crossover pipe, making sure balance of exhaust system is properly supported.
4. Remove oil pan attaching screws and lower rear of pan, turning it sideways to clear crossmember. *It may be necessary to pull the brake line (running across crossmember) slightly forward to allow enough clearance for pan removal. It is not necessary to remove the brake line. The oil pan drain plug must be removed.*

1959 Chrysler & Imperial

1. Drain oil and remove dipstick.
2. Disconnect steering linkage from steering arm to allow steering linkage to be lowered.

3. On single exhaust jobs, remove exhaust crossover pipe.
4. It may be necessary to pull the brake line slightly forward to allow enough clearance for pan removal. (Do not remove brake line which runs across crossmember.)
5. On Windsor models, unfasten and lower pan.
6. On other models, disconnect throttle linkage at transmission and at carburetor. Rotate crankshaft until centerline of front counterweight is at the 10 o'clock position. Remove front engine mount nuts and raise engine one inch. Then unfasten and remove pan.

1959 De Soto

1. On all models except Firesweep, after the oil pan screws have been removed, but the pan cannot be lowered all the way, it will be necessary to rotate the crankshaft until the front crankshaft throw is at the 4 o'clock position. This will permit the pan to be removed.
2. On Firesweep models, remove the front engine mounting nuts and raise the engine about one inch. The pan may then be lowered. *Whenever it is necessary to raise the engine for any reason, always disconnect the throttle linkage at the transmission as this will prevent damage to the throttle valve lever attached to the front valve body of the automatic transmission.*

Fig. 24 Chrysler and Imperial 1955-58 and 1955-57 De Soto

Fig. 23 Oil pump. 1959-62 Chrysler and Imperial and 1958-61 De Soto

1960-62

1. Disconnect battery cable and drain crankcase.
2. Raise car on hoist and disconnect steering linkage from idler arm and pitman arm.
3. Remove number 6 spark plug. (1960-61).
4. Remove outlet vent pipe and disconnect exhaust pipe branches from manifolds.
5. Remove clamp attaching exhaust pipe to extension and remove exhaust pipe.
6. Remove converter dust shield.
7. On 1960-61 New Yorker and Imperial, unfasten and lower pan. On all other models, remove the front engine mount nuts and raise engine two inches.
8. Remove oil pan bolts and turn flywheel until counterweight and connecting rods at the front end of crankshaft are at their highest position to provide clearance, and lower the pan. Turn the pan counterclockwise to clear oil screen and suction pipe.

OIL PUMP, REPLACE

1955-58 V8 Chrysler & Imperial & 1955-57 V8 De Soto

After removing the oil pan as outlined previously, unfasten the pump mounting bolts and drop the pump straight down and away from the engine.

When installing the pump, be sure to align the drive slot in the pump shaft with the distributor drive shaft. Install new seal rings and tighten the bolts with a torque wrench 30 to 35 lbs. ft.

1959-62 Chrysler & Imperial & 1958-61 De Soto

Remove oil pump attaching bolts and remove oil pump and filter assembly from bottom side of engine.

OIL PUMP REPAIRS

1959-62 Chrysler & Imperial & 1958-61 De Soto

To disassemble the pump, remove filter base and oil seal ring, Fig. 23. Remove pump rotor and shaft and lift out rotors. Remove oil pressure relief valve plug and lift out spring and plunger.

Wash all parts thoroughly. The mating surface of the oil pump cover should be smooth. Replace cover if it is scratched or grooved. Replace all worn parts and reassemble the pump.

1955-58 V8 Chrysler & Imperial & 1955-57 V8 De Soto

After removing the pump from the engine it should be disassembled, cleaned and inspected for wear or damage, Fig. 24.

1. Remove the cotter pin holding the oil strainer to the oil suction pipe. Then remove the pipe from the pump body.
2. Remove the pump cover and discard the oil seal ring.
3. Remove pump rotor and shaft and lift out rotor body.
4. Remove oil pressure relief valve plug and lift out the spring and plunger.
5. Wash all parts in cleaning solvent and inspect carefully for damage or wear.
6. The mating face of the oil pump cover should be smooth. If it is scratched or grooved, the cover should be replaced with a new one.
7. Check for excessive cover-to-rotor wear by laying a straight edge

across the cover surface. If a .0015" feeler gauge can be inserted between cover and straight edge, the cover should be discarded and a new one installed.

8. Measure the diameter and thickness of the rotor body with a micrometer. If the rotor body measures less than .998" and the diameter less than 2.244", install a new rotor body.
9. Measure the thickness of the pump rotor. If it measures less than .998", a new rotor should be installed.
10. Slide rotor body and rotor into pump body and then place a straight edge across the face of the pump body between the bolt holes. If a feeler gauge of more than .004" can be inserted between the rotors and straight edge, install a new pump body.
11. Remove the pump rotor and shaft, leaving rotor body in pump cavity. Press rotor body to one side with the fingers and measure the clearance between rotor and pump bodies. If it is more than .012", install a new pump body.
12. Check the clearance between the pump rotor and rotor body. If the measurement is more than .010", install a new pump rotor and rotor body.
13. Check the oil pump relief valve plunger for scoring and free operation in its bore. If the plunger is scored, install a new one.
14. When assembling the pump, be sure to use a new oil seal ring between the cover and body. Tighten cover bolts to a torque of 10 to 12 lbs. ft.
15. Prime the pump. Then place a new oil seal ring in the pump mounting face. Install oil pump and strainer and fasten the pump in position, tightening the bolts with a torque wrench from 30 to 35 lbs. ft.

Fig. 26 Water pump. 1959-62 Chrysler and Imperial and 1958-61 De Soto

RADIATOR, REPLACE

1955-56

Drain cooling system and disconnect hoses. Remove fan blades only if additional clearance is necessary. Unfasten radiator from its support and lift it out.

1957-62

If equipped, remove the two cooler connections at the bottom of the radiator and drain the oil from the oil cooler tank. Drain cooling system and remove hoses. On air conditioned cars, remove fan shroud. Take out radiator support bolts and lift out radiator.

WATER PUMP, REPLACE

1955

1. Drain cooling system.
2. Remove radiator inlet hose.
3. Remove heater hoses.
4. Remove wire from temperature gauge sending unit.
5. Remove fan shroud.
6. Remove idler pulley, fan, generator and fan assembly.
7. Remove radiator outlet hose from oil cooler and disconnect cooler from water pump (if equipped).
8. Remove screws which hold water pump housing to cylinder head and block.
9. If Air Conditioned, remove compressor bracket screws from water pump housing.
10. Remove water pump housing.
11. Reverse removal procedure to install and torque pump housing attaching bolts to 30 lb. ft.

1956

Drain cooling system and remove radiator and heater hoses. Remove fan shroud and disconnect wire at temperature gauge sending unit. Remove generator, fan, idler pulley and belts. Remove oil cooler (if equipped). Remove water pump.

1957-62

Drain cooling system, and on air conditioned cars only remove upper half of fan shroud. On 1958 De Soto and all

Fig. 25 Exploded view of 1956 water pump. On 1955 pumps a lock spring is used through a slot in the housing to position the bearing. The cover plate and fan pulley hub pin shown are not used on 1957-58 Chrysler and Imperial and 1957 De Soto pumps

Fig. 28 Ignition details. 1955-58 Chrysler and Imperial and 1955-57 De Soto

Fig. 29 Ignition details. 1959-62 Chrysler and Imperial and 1958-61 De Soto

1959-62 models it is necessary to remove the radiator. Loosen power steering pump or idler pulley, and generator. Remove all belts, fan, space and pulley.

On air conditioned cars, remove pulley from water pump fan hub, loosen all nuts from fan and remove the fluid fan drive.

On all models, remove bolts holding water pump body to housing and remove water pump.

WATER PUMP REPAIRS

1955

To disassemble the pump, first remove the bearing lock spring from the pump housing. Then after removing the impeller cover plate, position the pump in a suitable fixture with the impeller side up and, using a rod smaller in diameter than the bearing shaft, press downward on the shaft to remove the bearing and shaft assembly. Lift out the impeller and, after removing the impeller lock ring, take out the seal parts.

When reassembling the pump, a new seal and seal washer should be used. It is also advisable to replace the bearing and shaft since damage to this assembly usually results during its removal. The hub and impeller must fit tightly on the shaft; a hub that has been used previously usually does not fit tight enough.

1956

Referring to Fig. 25, remove the impeller cover plate. Press the shaft and bearing assembly out of the housing by pressing on the impeller end of the shaft. Remove the lock ring at the impeller and remove the seal parts.

The plastic impeller with which this pump is equipped cannot be re-used once it is disassembled from the pump. The impeller insert should be removed from the shaft before pushing the bearing out to prevent damage to the seal seat.

When assembling the pump, the impeller must be flush with the end of the shaft. The correct installed position of the hub is when there is .380" from the end of the fan pulley hub to the front end of the shaft.

1957-58 Chrysler & Imperial & 1957 De Soto

This pump has no cover plate nor does it use a lock pin to hold the fan pulley hub in place. To disassemble, use a suitable puller to pull the fan hub from the shaft. Remove the impeller by breaking the plastic away from the metal insert. Remove impeller insert and press the shaft and bearing assembly out of the housing from the impeller end. *Shaft and bearing assembly need not be removed to service a leaking pump.*

When assembled, the impeller should be flush with the end of the shaft. And when installing the fan pulley hub, press it on until there is .330" between the end of the shaft and the front face of the hub.

1959-62 Chrysler & Imperial & 1958-61 De Soto

If only the seal and impeller are to be replaced, support the pump assembly so that pressure is applied to the shaft. The bearings and shaft will be damaged if pressure is applied to the pump body. Fig. 26 is a disassembled view of the water pump.

To disassemble, support pump body on hub and remove impeller by breaking the plastic away from the metal insert. Remove the seal by sliding it over the shaft and insert. Remove impeller metal insert. Support body on front face (fan hub end), apply pressure to rear end of water pump shaft to press out bearing and shaft hub.

Reassemble the pump and be sure to obtain the dimensions indicated in Fig. 27.

Fig. 27 Water pump. 1959-62 Chrysler and Imperial and 1958-61 De Soto

DISTRIBUTOR, REPLACE

To remove the distributor, disconnect the vacuum control line and low tension wire and remove the cap and lock plate hold-down screw.

When installing the distributor, make sure that No. 1 piston is on top dead center on compression stroke and that the distributor rotor is in No. 1 firing position.

IGNITION TIMING

With the distributor properly installed on the engine as outlined previously, set ignition timing with a timing light so that with the engine idling, the timing light will flash when the pointer on the engine is opposite the timing mark on the vibration damper. Chalk-mark the spot on the vibration damper so that it stands out when the light flashes (see Figs. 28 and 29).

STARTER, REPLACE

Disconnect terminals from binding post and battery terminal or disconnect it at the battery. Then unfasten starter from flywheel housing and pull out starter.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A stuck valve in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work in the oil. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Engine Surge At Idle

Sonoramic Engines—Variations in engine idle speed may cause a loss of manifold vacuum which will actuate the anti-stall device, slightly opening the throttles. This may result in an undesirable "hunting" or surging condition. To eliminate the possibility of this condition it is recommended that the anti-stall device be adjusted as follows:

1. With accelerator linkage adjusted properly, adjust carburetor idle and mixture adjustments, being sure idle speed is 725-750 rpm in neutral with engine warmed up.
2. Disconnect vacuum tube at anti-stall device. Tape open end of the tube to prevent air leakage into the manifold. Disconnecting the vacuum tube will allow the anti-stall plunger to extend and increase engine idle speed.
3. Adjust anti-stall plunger length so engine speed is no higher than 1500 rpm.
4. Remove tape from vacuum tube and connect vacuum tube to anti-stall device. The plunger will retract and will permit engine idle to return to 725-750 rpm.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

CARTER NOTES

OVERDRIVE KICKDOWN SWITCH

BBD—With throttle valves wide open, there should be $\frac{1}{64}$" to $\frac{3}{64}$" clearance between kickdown lever and switch stem guide. To adjust, loosen lock nuts and adjust switch.

IDLE SPEED SETTING

Some 4-barrel carburetors do not have a conventional throttle speed screw but instead use an air adjustment screw. The idle air screw is located in the throttle body and can be identified by it being larger than the idle mixture screws. Turning the air screw outward increases engine speeds but also leans the mixture. This must be compensated for by adjusting the idle mixture screws.

METERING ROD

WCFB and WCD—This adjustment must be made after the pump setting. Seat throttle valves in bores of carburetor and loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—AFB float level. Adjust by bending float lever.

Fig. ②—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ③—Measure from top of bowl cover to top of plunger shaft with throttle connector rod in center hole of pump arm (AFB) or throttle lever (BBD). Adjust by bending throttle connector rod (AFB shown).

Fig. ④—With choke valve closed, tighten fast idle adjusting screw on high step of fast idle cam or on index mark until clearance between throttle valve and carburetor bore (side opposite idle port) is as specified.

Fig. ⑤—With throttle wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader lip on throttle lever (AFB shown).

Fig. ⑥—BBD float level. Adjust by bending lip on float arm.

Fig. ⑦—WCFB float level. Adjust by bending float arms.

Fig. ⑧—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑨—With pump connector link in center hole of pump arm, flat on pump arm should be parallel with a straightedge placed on dust cover boss. Adjust by bending throttle connector rod.

CARTER NOTES
continued

⑩—With choke valve tightly closed, there should be the clearance specified between throttle valve and carburetor bore (side opposite idle port). Adjust by bending fast idle adjusting tang, being sure tang is on high step of cam.

⑪—See ①. Ribbed floats $\frac{7}{32}$", smooth floats $\frac{5}{16}$".

⑫—With engine running at normal operating temperature, turn fast idle screw against index mark on cam or on high step of cam until specified rpm is obtained.

⑬—With engine running at hot idle speed and transmission in drive range, turn dashpot plunger toward bellcrank until the clearance specified is obtained.

⑭—Close throttle valves and bottom dashpot plunger with feeler gauge of the thickness specified between plunger and operating lever. To adjust loosen locknut and turn dashpot in or out as required.

⑮—Same as ⑨ except connector link goes in outer hole.

⑯—With choke valve closed and fast idle cam in fast idle position, there should be the clearance specified between throttle valve and carburetor bore (side opposite idle port). Adjust by bending choke connector rod.

⑰—Same as ③ except connector rod goes in outer hole.

STROMBERG NOTES

Fig. ①—WW float level. Invert main body so weight of floats only is forcing needle against its seat. There should be the distance listed from surface of fuel bowl to crown of float at center.

②—With throttle valve fully closed, measure pump travel from fully open to fully closed position. To adjust, bend pump rod.

③—With engine running at normal operating temperature, turn fast idle screw against highest step on fast idle cam until specified rpm is obtained.

Fig. ④—With throttle valves wide open, choke valve should open dimension specified between edge of choke va've and wall of air horn. Adjust by bending ear on throttle lever.

Fig. ⑤—This setting is made after pump travel setting. With throttle fully closed and choke valve wide open, test opening of bowl vent valve at center of hole with rubber valve hanging free. If not as specified, bend bowl vent lever as required.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1957 Chrysler & 1957-59 De Soto

To compensate for normal clutch wear, adjust the clutch release fork rod to obtain 5/32" free play of clutch release fork outer end. This will provide a one-inch the clutch assembly be exchanged for a free pedal movement at the pedal with a total of six-inch pedal travel.

When necessary to adjust the over-center spring, back off the over-center spring adjusting nut until it is free of the "C" link. With the clutch pedal depressed to the full six-inch travel, turn the adjusting nut until the nut just contacts the "C" link. Then tighten seven full turns from the fringe-tight position.

1955-56, Fig. 1

Adjust the clutch fork rod in or out as required to secure $\frac{3}{16}$" free play of the clutch release fork outer end. This will

Fig. 1 Clutch pedal and linkage. 1955-56

provide the one inch free pedal movement at the pedal pad with a total of 7″ full pedal travel.

The upper end of the clutch pedal pivots in the lower end of the mounting bracket on needle bearings. These bearings require no periodic lubrication. However, they should be lubricated with wheel bearing grease if the pedal is removed for any reason.

CLUTCH SERVICE

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If clutch rebuilding equipment is available, follow the equipment manufacturer's instructions.

Removal

1. Remove transmission and clutch pan.
2. Pull out clutch release bearing and sleeve.
3. Mark clutch cover and flywheel so they may be assembled in the same relative position and thus maintain original balance.
4. Remove cap screws which retain clutch cover to flywheel. Loosen each screw a few turns in succession until cover is free.
5. Clutch assembly and driven disc may now be removed from the clutch housing.

Installation

1. Coat the pilot bearing in crankshaft with wheel bearing grease.
2. Clean surfaces of flywheel and pressure plate, making certain no oil or grease remains on these parts.
3. Hold cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the crankshaft pilot bearing.
4. Bolt clutch cover loosely to flywheel, being sure marks previously made are lined up.
5. To avoid distortion of clutch cover, tighten cover bolts a few turns each in progression until all are tight. The final tightening should be 15-20 lb. ft. torque.
6. Install transmission by guiding it into place with guide studs inserted in the two top holes of the clutch housing.
7. Adjust clutch pedal free travel.

TRANSMISSION, REPLACE

It is not necessary to remove the floor boards.

1. On cars without overdrive, disconnect propeller shaft at front. (On cars with overdrive, remove propeller shaft and both universals. Remove solenoid and disconnect control cable.)

2. On all cars, disconnect speedometer cable, hand brake cable, and gearshift rods from transmission.

3. Remove two upper transmission mounting studs and insert guide pins in their place.

4. Remove other mounting studs and slide the transmission back and out.

When installing, use the guide studs and handle the transmission carefully to avoid damage to the clutch disc.

TRANSMISSION REPAIRS

(For detailed service on overdrive transmissions, see the *Overdrive* chapter. To disassemble the standard transmission, see Fig. 3 and proceed as follows:

1. Remove speedometer drive pinion.

Fig. 2 Cross section of typical clutch

Fig. 4 Shifting plates (2) fit in stop ring slots (1)

Fig. 5 Installing synchronizer shifting plates and spring spring on standard transmission. 1. Shifting plates. 2. Spreader spring. 3. Clutch sleeve. 4. Clutch gear

Fig. 6 Mainshaft and extension on standard transmission. 1. Snap ring. 2. Clutch sleeve. 3. Second speed gear. 4. Extension. 5. Clutch gear. 6. Mainshaft. 7. Sliding gear

Fig. 3 Synchromesh transmission

2. Take off cover and gear selector, roll transmission over and remove balls.
3. Use a puller to remove mainshaft flange and brake drum.
4. Remove shifter fork guide rail.
5. With gears in neutral, remove shift fork lock screws.
6. Remove plug for lower shift rail.
7. Slide shift rails out through front of case.
8. Lift out shift forks.
9. Remove extension housing and mainshaft, being careful not to allow synchronizer to become disassembled.
10. Strip mainshaft of synchronizer, second speed gear and sliding gear.
11. Release snap ring and pull mainshaft out of extension housing.
12. Remove mainshaft bearing, spacer and speedometer drive gear.
13. Pull bearing and oil seal from extension housing.
14. Drive countershaft through rear of case, allowing cluster gear to lie in case.
15. Remove main drive gear and bearing and disassemble parts.
16. Lift out cluster gear and related parts.
17. Drive reverse idler shaft out rearward and lift out gear.

Assembly Notes

Use new gaskets, oil seals and snap rings, being sure snap rings fit snugly in their grooves.

When assembling cluster gear, place steel washer plates next to gear and bronze washers next to case. Select the proper thickness bronze washers to provide end play of from .002 to .008 inch.

If a special oil seal drift is not available, be sure that oil seal protrudes $\frac{7}{32}$ inch out of the mainshaft extension housing.

Referring to Figs. 4 and 5 for synchronizer assembly, place one bent up end of synchronizer spring into pocket of shifting plate. Then install bent up end of other spring into pocket of same plate on opposite side of synchronizer. Spring on one side should leave plate in opposite direction from spring on other side.

Assemble the synchronizer unit on the mainshaft as shown in Fig. 6.

If second speed gear end play is not within .003 and .008 inch, use a snap ring of different thickness.

Install first and reverse shifter rail (1, Fig. 7) on top, other rail on bottom.

Install gearshift housing as shown in Fig. 8.

GEARSHIFT, ADJUST

1955-56 Manual Trans.

To adjust the control rod, loosen the lock bolt at the upper lever on the lower end of the steering column. Set the transmission gears in neutral and the hand control lever in the horizontal position and tighten the lock bolt.

To adjust the shift control rod, set the transmission gears in neutral and loosen the lock nut on the selector rod at the transmission end. Tighten the nut until all play is eliminated and back off ½ turn for clearance and tighten.

Fig. 7 Shift rails on standard transmission. 1. First and reverse. 2. Second and high

1957-61 Manual Trans.

This transmission incorporates an individual rod shifting mechanism, Fig. 9, which simplifies maintenance, improves shift quality and decreases shifting effort.

Cross-over adjustments and gearshift operating lever positions are adjusted by threads on the upper ends of the shift rods. Movement of the shift lever should be smooth when moving through the cross-over position.

If an up and down motion at the hand lever is experienced during cross-over, the shift rod length should be adjusted by turning the adjusting nuts on one rod to vary the trunnion position on the rod. This will raise or lower the lever at the lower end of the steering column and thus align the cross-over. The hand lever knob must be in a horizontal position following cross-over adjustments.

If the lever binds when moving into a gear position after cross-over, check the position of the gearshift tube support at the lower end of the steering column. The support should be moved up to relieve binding on the second-to-high side and down for the low-to-reverse side.

Cross-Over Adjustments

Before making the cross-over adjustment, Fig. 10, the gearshift lever shaft must be in its normal fully returned position in neutral. Then proceed as follows:

1. Remove grease fitting from tube lever pin retainer. Rotate retainer until gearshift tube cross pin is exposed.
2. If a .040″ round feeler cannot be inserted between pin and bottom of slot as shown in Fig. 10, an adjustment at the gearshift tube lower support must be made as follows:
3. Loosen lower support screws slightly. Move support by tapping lightly with a plastic hammer.
4. Adjust support up or down as required to secure the necessary .040″ clearance.
5. Tighten support clamping screws to 150 *inch* lb. torque (90 *inch* lb. for power steering equipped cars).
6. Rotate tube-lever pin retainer to original position and install grease fitting securely. (Loss of fitting will result in loss of cross pin).

Control Rod Adjustments

After completing foregoing adjustments, be sure gearshift lever travels freely and equally up and down in either high or second gear position and low or reverse positions. Check the cross-over adjustments, Fig. 11, with the manual lever by making the cross-over from second-to-direct and from low-to-reverse. Cross-over must be free of interference. Transmission must be in neutral when making the following adjustments:

1. Loosen adjusting nuts at second-to-direct control rod swivel.
2. Turn both adjusting nuts in direction required to locate hand lever in horizontal plane.
3. Tighten adjusting nuts securely to swivel block.
4. Loosen adjusting nuts at low-to-reverse gearshift control rod swivel.
5. Position low-to-reverse gearshift lever in direct alignment (through center of swivel lock pin) with second-to-direct gearshift lever. Tighten adjusting nuts securely to swivel block.

Caution: Failure to make this adjustment correctly will result in insufficient manual lever-to-steering column clearance or manual lever-to-operator's leg clearance. Damage to the transmission is also possible because of incomplete engagement of gears.

1962 Chrysler

1. Disconnect choke at carburetor or block choke in full open position.

Fig. 9 Manual transmission shift linkage. 1957-61

Fig. 10 Checking gearshift lever shaft in Neutral position. 1957-61

Fig. 11 Gearshift control rod adjustments. 1957-61

Fig. 8 Installing gearshift housing. 1955-56. 1. Gasket. 2. Screw. 3. Housing. 4. Pilot studs

Fig. 12 Powerflite push button control unit

Fig. 13 Removing push button control cable from Powerflite transmission (oil pan removed to show operation)

2. With lock nut loose in carburetor rod, insert a $\frac{3}{16}$" diameter rod approximately 10 inches long through the holes in the bellcrank bracket and lever assembly (see Fig. 19).
3. Tighten carburetor rod lock nut.
4. Disconnect one end of accelerator pedal rod. Adjust its length to provide a pedal angle of 113° to 115°. Reinstall rod.
5. Remove the $\frac{3}{16}$" rod.
6. Connect choke rod or remove blocking fixture.

POWERFLITE

A detailed service procedure on this transmission is given in the *Automatic Transmission Section* of this manual.

Transmission, Replace

1. Drain transmission and converter.
2. Disconnect front universal and secure propeller shaft to frame.
3. Remove hand brake linkage.
4. Disconnect speedometer cable, neutral starter and back-up light wires from switches.
5. Disconnect throttle linkage from lever at transmission.
6. Remove push button control cable (if equipped).
7. Remove oil cooler lines (if equipped).
8. Remove nuts from rear engine mount and support engine with a suitable jack.
9. Remove crossmember, leaving engine rear support adapter attached to transmission.
10. Unfasten transmission from converter housing and slide it straight back and out of car.
11. Reverse foregoing procedure to install.

POWERFLITE LINKAGE

Selector Linkage, 1955

The selector lever is held in a gate between "N" and "D" positions under tension which is adjustable by a bracket to which it is attached behind the instrument panel. Use a spring scale and pull out the selector lever knob, which should require one to two lbs. pull on the scale to break contact between selector lever and gate. If it does not, adjust by loosening the bracket attaching bolts and slide the bracket to obtain the desired tension. Tighten bolts and recheck tension.

If correct tension cannot be obtained by adjusting the bracket, it can be corrected by removing the selector lever and mounting bracket and bending the tension spring. Bend the spring away from the gate to decrease tension and toward the gate to increase tension. If binding still exists, investigate the linkage and correct as required.

Throttle Linkage, 1955-57

Correct any binding condition in linkage before proceeding. Engine must be at operating temperature (off fast idle) and idle speed set to 475-500 rpm. Stop engine and loosen throttle linkage adjusting screw, located on accelerator shaft-to-carburetor rod. Move rear portion of rod rearward until stopped by the idle stop on the transmission throttle cam. With rods in line and rear portion slightly pre-loaded, lock throttle linkage adjusting screw securely.

Throttle Linkage, 1958

Correct any binding condition before making any adjustments. Engine must be at operating temperature (off fast idle) and idle speed set to 475-500 rpm in neutral.

Stop engine and loosen throttle linkage adjusting nuts on carburetor-to-bellcrank rod and on bellcrank-to-transmission rod. Adjust carburetor-to-bellcrank rod to position the lever ½" from the firewall (see "A", Fig. 17) and tighten adjusting nut. Hold a slight pre-load rearward on bellcrank-to-transmission rod while holding transmission throttle valve lever forward against the stop and tighten adjusting nut.

The accelerator pedal should be at an angle of approximately 118 deg. to the horizontal ("C" Fig. 17). If necessary to adjust pedal angle, remove accelerator pedal end of bellcrank-to-pedal rod and shorten or lengthen the rod by loosening the lock nut at the swivel end. Rotate swivel until proper rod length is obtained. Reinstall rod and tighten lock nut. The straight portion of the bellcrank-to-transmission rod is approximately 6½" long as indicated at "B", Fig. 17, measured from bellcrank end to center of bend.

Fig. 14 Control cable backlash adjustment. Powerflite

Fig. 14A Wheel-type push button cable adjustment. 1959-62 Torqueflite

Throttle Linkage, 1959-61

Throttle linkage adjustment remains essentially the same as for 1958 models with the following exception:

Placing a pin through an appropriate slot and hole (in lever and bracket) will set the correct angle of the lever for easier adjusting of the entire throttle linkage. Also, on 1960-61 models, dimension "B" as shown in Fig. 17, does not apply as the rod is shaped differently.

POWERFLITE PUSH BUTTONS

1956-61

Mechanical connection between the push button unit, Fig. 12, and the manual control valve is obtained through the use of a single push-pull cable. One end of the wire cable is secured to the cable actuator in the speed range selector unit on the instrument panel. The other end enters the transmission case to engage the manual control valve assembly.

Cable Remove, Push Button End

Remove bezel attaching screws, then remove bezel and push buttons. Remove nuts holding push button unit to instrument panel and remove push button unit from rear of panel. The cable bracket is held by two screws to the push button unit. A hairpin clip secures the cable to the actuator bar.

Cable Remove, Trans. End

Remove throttle adjustment hole plug and allow transmission fluid to drain off to the level of the hole. Remove neutral starter switch to provide access to the cable lock spring. Remove cable bracket. Insert screwdriver through neutral switch hole. Push gently on projecting portion of cable lock spring and pull outward on cable, Fig. 13. On star wheel type, push "R" button in to place cable adapter near switch hole.

Cable Install, Trans. End

Push in "L" button. Place transmission manual valve lever in reverse detent by moving neutral switch contact part of lever full travel towards rear of car

Fig. 15 Torqueflite push button control unit

manually, by using a screwdriver in neutral starting switch hole. With "L" button held tightly in, insert cable into transmission case engaging cable ferrule groove with lock spring in cable adapter. Push and pull the cable, using pressure, to be sure groove in cable ferrule has engaged lock spring. Replace mounting bracket and tighten cap screw finger tight.

Cable Adjustment

Loosen and move cable and bracket assembly manually at the transmission as required, to position manual valve lever into neutral. Hold "N" button tightly in at full travel. The neutral starting switch cam should then be practically centered in its mounting hole. Use a free fitting flat nosed rod, inserted through the neutral switch mounting hole, and apply light pressure against the manual valve lever to maintain the neutral detent position of the manual lever. Carefully move cable assembly in and out, without moving the manual lever, to determine total free-play travel of cable. Locate the cable in mid-position of the free-play, Fig. 14, release the pressure against the manual lever and tighten the mounting bracket securely. *Do not allow the cable to move when tightening the bracket or backlash setting will be disturbed.* Replace neutral switch and check fluid level.

TORQUEFLITE

A detailed service procedure on this transmission is given in the *Automatic Transmission Section* of this manual.

Transmission, Replace

1. Disconnect battery.
2. Place push button in "1" position ("R" position on 1960-62) so as to be able to remove cable from adapter housing on transmission.
3. Drain transmission and converter.
4. Disconnect front universal joint.
5. Disconnect hand brake linkage.
6. Disconnect speedometer cable.
7. Disconnect neutral starter switch wire.
8. Disconnect throttle control linkage at transmission.
9. Loosen push button control cable adjustable mounting bracket or adjustment wheel locking screw.
10. Remove control cable adapter housing plug, insert screwdriver through hole, release cable spring lock and remove cable from adapter housing.
11. Using same screwdriver, insert through cable opening in housing and push lever rearward to last detent. Then reinstall housing plug and tighten.
12. Remove oil cooler lines from transmission (if equipped).
13. Unfasten rear engine support from crossmember.
14. Remove starting motor.
15. Support engine with suitable jack.
16. Raise engine slightly and remove crossmember.
17. Unfasten and remove transmission from converter.
18. Reverse foregoing procedure to install transmission.

TORQUEFLITE PUSH BUTTONS

Wheel-Type Cable, 1959-62

1. To remove the cable, drain approximately three quarts of oil from the transmission.
2. Engage "1" push button.
3. Remove adjusting wheel lock screw, Fig. 14A.
4. Remove neutral starter switch, cupped washer and seal.
5. With a screwdriver inserted through neutral starter switch opening, push gently against the upward projecting portion of the control cable adapter lock spring and pull outward on cable to remove cable assembly from case.

Install and Adjust

1. Engage "R" push button. *Have an assistant hold this button firmly until the transmission end of the cable has been adjusted and locked.*
2. Back off the cable adjustment wheel (turn counter-clockwise) on cable housing until only two or three threads are showing. *Caution: do not back the wheel entirely off the guide threads because it serves as a stop to prevent the "O" ring from going too far into the case and becoming caught inside the case when the cable is installed.*
3. Push cable control housing into the transmission case with just enough force to overcome the "O" ring friction and to bottom the assembly. While holding the cable firmly into the bottomed position, rotate adjusting wheel clockwise *to just contact the transmission case.*
4. Release the inward pressure on the cable and then turn the adjusting wheel until the next adjustment hole in the wheel lines up with the lock screw hole in the case. Counting this hole as number one, continue turning the wheel clockwise until the fifth hole lines up with the screw

Fig. 16 Torqueflite manual control cable adjustment (non-wheel type)

hole in the case. Check cable adjustment to be sure of full detent in all shift ranges.
5. Install neutral starter switch and refill transmission with oil.

Non-Wheel Type Cable, 1959

1. Engage "R" button and hold in this position.
2. Loosen cable adjusting clip screw.
3. Move cable into transmission as far as it will go and turn cable adapter lock screw (left hand thread) counter-clockwise until it bottoms. This will hold lever in reverse detent position.
4. Move cable in and out and position cable in center of this free travel.
5. Tighten cable adjusting screw clip to 30-50 *inch* lbs. torque.
6. Turn cable adapter lock screw out (clockwise) until it is seated at from 10-16 *inch* lbs. torque. This will seal the lock screw plug and prevent oil leakage around the lock screw threads.

Cable Adjust, 1957-58

1. Referring to Figs. 15 and 16, first engage the "R" button.
2. Drain two quarts of fluid from transmission.
3. Loosen cable adjusting clip screw.
4. Remove neutral starter switch.
5. Insert screwdriver through neutral switch hole and pry lightly on lever to hold lever in reverse detent position.
6. Move cable in and out while observing the amount of free travel, then position cable in the center of this free travel.
7. Tighten adjusting screw clip, install neutral switch and replenish transmission fluid.

TORQUEFLITE THROTTLE LINKAGE

1956-57 Four Bar. Carb.

1. Check accelerator pedal angle to make sure it is 118 degrees from the horizontal. Proper pedal angle is obtained by adjusting the pedal to shaft rod length at the ball joint on the pedal end. Check and correct any binding condition in the throttle linkage.
2. Run engine until normal operating temperature is reached. Remove air cleaner and check to see that choke valve is wide open.
3. Connect tachometer to coil and ground.
4. With engine idling in neutral, adjust engine idle screw to give 475-500 rpm, and stop engine.
5. Loosen throttle linkage adjusting nut located on the rod accelerator shaft to intermediate shaft.
6. Move rod rearward against idle stop on transmission throttle cam.
7. With rod pre-loaded and in line, lock throttle linkage adjusting nut and torque to 7-9 lb. ft.
8. Start engine and recheck idle speed setting with transmission in neutral and hand brake applied.

Fig. 17 Throttle linkage adjustment. 1958 Torqueflite and Powerflite

Fig. 18 Throttle linkage adjustment. 1960-61 Ram Manifold

1956-57 Two Bar. Carb.

Adjustment procedure is the same for the two-barrel carburetor except Steps 4, 6 and 7, which are performed in the following manner:

1. Loosen throttle linkage adjusting screw, located on accelerator shaft-to-carburetor rod.
2. Move rear portion of carburetor rod rearward until it is stopped by the idle stop on the transmission throttle cam.
3. With rods in line and rear portion of rod pre-loaded, lock throttle linkage adjusting screw and tighten to a torque of 7-9 lb. ft.

Note—Some vehicles may be equipped with a throttle linkage adjustment at the transmission throttle operating lever. The purpose of this adjustment is to allow for variations between chassis and engine assemblies in the manufacturing of different models and should not be used for making the throttle linkage adjustment.

1958 Four Bar. Carb.

1. With engine at operating temperature and choke valve wide open, adjust idle speed to 475-500 rpm with transmission in neutral.
2. Loosen throttle linkage adjusting nuts on carburetor-to-bell crank rod, and on bell crank-to-transmission rod.
3. Adjust carburetor-to-bell crank rod to position the lever ½" from the cowl dash panel and tighten adjusting nut (see "A", Fig. 17).
4. Dimension "B", Fig. 17, should be 8½". Hold slight pre-load rearward

Fig. 19 Throttle linkage. 1962 Chrysler with manual or automatic transmission

on bell crank-to-transmission rod while holding the transmission throttle valve lever forward against the stop, and tighten adjusting nut.

5. The accelerator pedal height should be at an angle of 115 degrees (see "C", Fig. 17) to the horizontal. If necessary to correct, shorten or lengthen pedal rod at the swivel. Reinstall rod and tighten lock nut.

1958 Two Bar. Carb.

All operations are the same as the four barrel carburetor except that, since there is no intermediate throttle control assembly, adjustment is made on the bell crank-to-carburetor rod.

1959-61

Throttle linkage adjustments remain essentially the same as for 1958 models with the following exception:

Placing a pin through the appropriate slot and hole (in lever and bracket) will set the correct angle of the lever for easier adjusting of the entire throttle linkage. Also, on 1960-61 models, dimension "B" as shown in Fig. 17, does not apply as the rod is shaped differently.

1960-61 Ram Manifold

Refer to Fig. 18 and perform the following operations to properly adjust the linkage:

1. Loosen adjusting nuts "A" and "B".
2. Insert a $\frac{3}{16}$" drill rod, 10" long into the accelerator shaft bracket and through the hole in the lever.
3. Move transmission throttle control lever forward until it stops and tighten locknut "A" securely. This positions accelerator shaft.
4. Unsnap accelerator pedal to shaft rod.
5. Turn threaded end of rod in or out to obtain 114° angle between floor of car and flat face of accelerator pedal and connect rod.
6. Remove drill rod from accelerator shaft bracket.
7. Inspect carburetors to be sure that choke valves are open, fast idle cams are released and throttle valves are closed.
8. Loosen locknuts "C" and "D" and back off anti-stall plunger far enough to allow bellcrank to be pivoted.
9. Pivot bellcrank until a $\frac{3}{16}$" drill rod, 3" long can be inserted through bellcrank hole and down into intake manifold.
10. Tighten locknuts "C" and "D" and remove the drill rod from the bellcrank.
11. Push rearward on the accelerating shaft to throttle shaft lever rod adjusting link until stop is reached and tighten locknut "B" securely.

1962

1. Referring to Figs. 19 and 20, disconnect choke at carburetor or block choke in full open position. Open throttle slightly to release fast idle cam, then return throttle to slow idle position.
2. With lock nuts loose on carburetor and transmission rods, insert a $\frac{3}{16}$" diameter rod approximately 10 inches long through the holes in the bellcrank and lever assembly.
3. Move transmission lever forward against the stop and tighten transmission rod lock nut.
4. Disconnect one end of the accelerator pedal rod. Adjust its length to provide a pedal angle of 113° to 115°. Reinstall rod.
5. Remove $\frac{3}{16}$" rod. Move link of carburetor rod rearward until transmission lever stop is contacted. Tighten carburetor rod lock nut.
6. Connect or unblock choke.

Fig. 20 Throttle linkage. 1962 Imperial

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

CAGE-TYPE REAR AXLE

The drive pinion in this unit, Fig. 1, is held in position by the shoulders in the differential carrier upon which the pinion bearing cups seat. The pinion position is maintained by a washer or shims located between the pinion head and the rear bearing cone. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

Cross and roller universal joint

Pinion & Bearings, Replace

The differential unit must be removed before the drive pinion can be taken out, but it is not necessary to remove the drive pinion or differential unit if only the drive pinion bearing oil seal is to be replaced.

To remove the oil seal, take off the pinion flange retaining nut and use a suitable tool to remove the flange. The oil seal may then be pulled out of the carrier.

Pull the drive pinion through the gear end of the differential carrier. The bearing spacer, front bearing and shims may then be taken out. Using a bearing puller, remove the rear bearing cone from the pinion shaft and, unless the ring gear and pinion are to be replaced with new parts, use care not to allow the front and rear shim packs to become mixed.

If the differential unit was satisfactory from the standpoint of noise before the unit was dismantled, the drive pinion may be assembled with the original shims (or washer) behind the rear bearing. If new parts are used or if an adjustment was necessary, change the shims until the correct combination is obtained to locate the pinion properly.

To assemble, place the front bearing in position in its cup and install the pinion shaft oil seal, using a suitable tool. Place the washer or shims on the pinion shaft against the pinion head and press on the rear bearing. Slip the bearing spacer against the rear bearing, then place the front bearing shims ahead of the spacer. Install the pinion and assembled parts in the carrier, passing the forward end of the pinion through the front bearing. Replace the pinion flange, slip on the washer, screw on the retaining nut and tighten securely.

Fig. 1 Rear axle with cage-type differential

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearings are tight, but still permit rotating the pinion by hand.

The pinions should be pre-loaded .0015-.0025 inch. To check and adjust this preload (tension) mount a dial indicator on the carrier with the stem of the indicator contacting the pinion flange. Then if the indicator, for example shows .004 inch end play, remove the parts including .006 inch of shimming to give the necessary .002 inch draw tension or preload on the bearings.

Fig. 6 Rear axle with bolt-on type barrel differential. 1955-57

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion should be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle* chapter. If a correction is necessary, disassemble the parts and, if the pinion is to be moved toward the center of the axle, add shims or install a thicker washer (whichever is used) between the pinion head and the rear bearing cone. If the pinion has to be moved away from the center of the axle, remove shims or install a thinner washer.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle* chapter. When the adjustment is correct, install a new cotter pin in the pinion retaining nut.

SCREW-ON BARREL DIFFERENTIAL

Fig. 2 shows the differential driving unit employed on the above models. The drive pinion is held in place by the shoulders in the differential carrier, upon which the pinion bearing cups seat. A washer between the shoulder on the pinion shaft and the front bearing cone controls end play in the pinion bearings.

The ring gear and pinion are precision machined when manufactured so that no shims or washers are needed to make adjustments for pinion position.

A thrust pad, which presses against the back face of the ring gear, together with the rigid differential case design, maintain accuracy of mesh between the ring gear and pinion.

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as replacing the ring gear and checking ring gear and pinion backlash, is given in the *Rear Axle* chapter.

Note—Except for the differential case. all service work is the same as described for the unit used on other Chrysler models.

Differential Case, Overhaul

Mount the differential case ring gear flange in a vise using copper jaws. Remove the bearing from the differential case cap side only. Remove differential case cap locking pins, Fig. 3, by center punching and drilling. Remove shell of pins left in hole with a punch.

Since the cap is a thousandth or two larger than the hole in the case which it fits into, case must be expanded for removal of cap or damage will result.

Heat the case (not cap) by playing a torch around the outside. Keep the flame moving to assure even heating. Try a piece of ordinary solder on case from time to time and when solder just starts to melt, the case is as hot as it can get without damaging inside washers.

When the case is just hot enough to melt soft solder, remove the cap, using a blunt drift and heavy hammer. If the special wrench shown in Fig. 4 is available, jar the cover loose by means of a smart blow on the wrench handle and then unscrew the cap. The parts now can be immersed in oil to cool them for subsequent handling.

Remove the differential pinion shaft lock pin by driving it out of the case with a hammer and punch, Fig. 5. When installing this pin, be sure to peen over the outside edge of the hole to lock the pin in place.

Push the differential shaft out of the differential case. The gears, thrust washers and axle shaft thrust block will then be loose and fall out of the case.

When assembling, coat all parts with differential lubricant to facilitate holding them in place until the thrust block and differential pinion shaft are installed. Heat the case as outlined above and install the case cap, tightening it rigidly with the spanner wrench, Fig. 4, if available, or else with a punch and hammer. Drill new ¼ in. holes in the cap and install new (unused) lock pins.

Fig. 7 Wheel bearing and axle shaft details. All models

Ring Gear Thrust Pad

This pad, Fig. 2, assists in maintaining the mesh of the ring gear and pinion. After all other adjustments have been made, turn the pad adjusting screw in until it just contacts the back face of the ring gear and then back it off about ⅛ turn, locking the adjustment with the lock nut.

BOLT-ON BARREL DIFFERENTIAL

Fig. 6 is a layout of the parts that make up this unit. Service-wise, it is the same as the screw-on barrel type except that the differential is unbolted from the cap. In all other respects, the unit is serviced in the same manner as the other types.

AXLE SHAFT & OIL SEALS

Fig. 7 shows the details of the new type outer oil seal employed on these models. To remove, take off the wheel, hub and drum. Then disconnect the brake tube at the wheel cylinder, and remove the brake support. Drive out the old seal and remove the burrs from the support plate to prevent damaging the new seal.

With the brake support removed, install the new seal from the outer side of the brake support plate. Then stake the plate in three places with a center punch to hold the seal in position. Install the special tool, Fig. 8, in the seal or use other suitable means to protect the leather portion of the seal from being damaged by the axle shaft keyway and install the brake support as shown. Remove the tool and complete the installation of the brake support, hub and drum and wheel.

To remove the axle shaft and inner oil seal, disconnect the brake line and remove the wheel hub and drum assembly. *Do not use a knock-out type puller or strike the ends of axle shafts to loosen wheel hubs as this may damage the bearings.* Remove the axle shaft keys and install the special sleeve shown in Fig. 8 to protect the seal while removing brake supports, seals and bearing shims. Keep each set of shims separate to assure proper assembly. Use a suitable puller to remove the axle shaft and bearing from the housing. Then pull the inner seal from the housing.

To adjust axle shaft end play, add or remove shims as required to obtain the desired end play. When adjusting bearings, remove or install an equal thickness of shims on the right and left sides of the axle housing to maintain central position of shaft thrust block.

1957-62 Service Note

As indicated in the *Rear Axle Specifications* table, the end play clearance is absolutely essential in order to allow for lengthwise expansion of axle shafts as temperatures increase during normal driving. If end play is not within the limits of .013″ to .023″, adjust to .018″. If end play is less than .013″, it is possible that the normal heat expansion of axle shafts may tend to preload the axle shaft bearings and reduce bearing life.

BRAKE MASTER CYLINDER, REPLACE

1955-62

To remove the master cylinder, remove pedal return spring. Disconnect push rod, brake line tube at master cylinder, and stop light switch wires. Unfasten cylinder from its mounting and remove from dash panel.

POWER BRAKE

1956-61 Bellows Type

To remove the unit, use a pedal depressor to depress the pedal to prevent the trigger arm from extending beyond the extremities of the bracket. *If the pedal linkage is allowed to extend through the hole in the dash panel the trigger arm may be damaged.*

Disconnect the vacuum hose at the power vent. Remove the master cylinder power unit and bracket from dash panel.

Fig. 8 Installing axle shaft outer oil seal with special sleeve

Use care to prevent loss of nylon bushing on pedal linkage cross pin.

Reverse foregoing procedure to install the unit.

1956 - 61 Cylinder Type

Place a wood wedge between power brake lever and forward edge of triangular hole in pedal bracket to prevent trigger arm from extending beyond extremities of bracket. *If pedal linkage is allowed to extend through dash panel the trigger arm may be damaged.*

Disconnect vacuum hose at power unit. Unfasten and remove power unit from dash.

1962

1. With the engine not running, pump the brake pedal about six times to destroy the vacuum stored in the booster.
2. Disconnect booster push rod from brake pedal by removing one nut and shoulder bolt.
3. Disconnect hydraulic line from master cylinder.
4. Disconnect vacuum line from vacuum check valve at top front of front shell of booster housing.
5. Disconnect booster from firewall reinforcement plate by removing four stud nuts from passenger compartment side of firewall.
6. Remove booster and master cylinder assembly from vehicle as a unit. A plastic gasket is used between booster and plate. Discard this gasket; a new one is part of the replacement package. *The booster will be serviced as a unit with the exception of the vacuum check valve and vacuum seal.*

Front End and Steering Section

CAMBER & CASTER, ADJUST

1959-62

Caster and camber adjustments are accomplished by means of the upper control arm attaching bolt and cam assemblies, Fig. 1.

To adjust caster and camber, carefully loosen the upper control arm adjusting bolt nuts while holding the bolts to prevent turning. Record caster and camber readings.

Adjustment of caster through camber readings is possible because of the consistent relation between caster change and camber change when either the front or rear cam bolt at each control arm is individually rotated.

Turning one bolt affects caster more than camber. Turning both bolts an equal amount in the same direction affects camber directly, and caster indirectly. Turning the cams an equal amount in opposite directions will change caster with little change in camber, depending on the relative position of the cams.

By bringing caster within specifications by turning one bolt at a time, then by turning both bolts an equal amount to bring camber to the preferred reading, the caster will usually be brought close to the preferred setting.

After both caster and camber readings are correct, tighten the nuts to a torque of 65 lbs. ft. while holding the bolts from turning.

Always recheck the settings after tightening the nuts since the bolts may have turned slightly during the tightening process.

Service Note

The direction the cam is turned initially depends upon the position of the high spot of the cam. The procedure is to turn the eccentric in either direction until the desired movement takes place. If you continue turning past the high spot of the cam the movement will start to reverse. In other words, the high spot is the limit of adjustment in either direction.

Fig. 1 Upper control arm and frame brackets. 1959-62

1957-58

Adjustments are performed by installing $\frac{1}{16}$" and $\frac{1}{32}$" shims between the upper control arm support brackets and the frame sub-side rails. Installing or removing shims at either the front or rear bracket changes the *caster* setting. Installing or removing shims equally at both brackets changes the *camber*.

Raise the car from the floor and loosen the upper control arm support bracket bolts. Add or remove shims as required and tighten bolts. *Adding shims equally at both front and rear support brackets will decrease positive camber.* One shim $\frac{1}{16}$" thick at each bracket will change camber $\frac{5}{16}$ degree.

Addition of shims to the front bracket or removal of shims at the rear bracket will decrease positive caster. One shim $\frac{1}{16}$" thick will change caster approximately ½ degree. Total thickness of each shim pack should *not* exceed $\frac{9}{16}$".

After lowering car, jounce front end up and down a few times before rechecking wheel alignment to allow suspension to assume normal position.

1955-56

Caster angle is not adjustable but the proper setting is obtained when assembling the camber eccentric bushing. To adjust camber, loosen the clamp screw and turn bushing to obtain the correct setting within a half revolution from the point where the correct caster setting is obtained. Do not turn the bushing until it binds against the upper control arm. Keep the steering knuckle support as nearly central as possible.

Fig. 2 Torsion bar suspension

TOE-IN, ADJUST

1955-61

With the steering wheel in its mid-position, and the center spoke of the steering wheel horizontal, turn both tie

Fig 3. Torsion bar spring cam and height adjustment. 1957-59

rods an equal amount until the toe-in is correct.

1962

With the front wheels in straight ahead position loosen the clamps at each end of both adjusting tubes. Adjust toe-in by turning the tie rod sleeve which will "center" the steering wheel spokes. If the steering wheel was centered, make the toe-in adjustment by turning both sleeves an equal amount. Position the clamps so they are on the bottom and tighten bolts to 15 ft. lbs.

WHEEL BEARINGS, ADJUST

1. Tighten wheel bearing adjusting nut to 90 inch pounds torque while rotating wheel.
2. Position nut lock on nut with one pair of slots in line with cotter pin hole.
3. Back off lock and adjusting nut to next slot.
4. Install cotter pin. The resulting adjustment should be zero to .003" end play.
5. Clean grease cap, coat inside with wheel bearing grease (do not fill) and install cap.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure that the front wheel bearings are properly adjusted and that the control arms are tight.

Although Chrysler publishes no specific recommendations, a reliable method is to jack up under the lower control arm near the outer end. Then grasp the tire at the top and bottom and move it in and out. If wheel movement or play in excess of ¼" is evident, replace the joint or joints as required.

TORSION BAR SUSPENSION

Service Note

1. When necessary to install new torsion bars, remove all accumulated dirt, scale and moisture from inside torsion bar rear anchor.
2. Do not apply heat to anchor assembly in order to remove bar. Use an arbor press to remove bar from anchor whenever necessary.
3. Coat inside of anchor with multipurpose grease.
4. The torsion bars have a pre-set loading for right and left usage. Bars can be identified by the letter "R" or "L" stamped on one end of bar. This letter is not visible when the bar is installed. However, the last three digits of the part number can be seen from the anchor end of the bar; the left bar is stamped with the odd number, the right bar with the even number.
5. Always install new torsion bar rear anchor seal.
6. In every case where a bar is being replaced for breakage, apparently as a result of corrosion within the rear anchor, it should be assumed that the other bar would be in a similar condition, and both bars should be replaced.
7. The torsion bar adjusting bolt should only be loosened (or tightened) with a foot pound torque wrench with vehicle supported under frame to relieve load on torsion bars. If more than 200 ft. lbs. is required to turn the adjusting bolt, then the bolt and swivel must be replaced.
8. If the vehicle is to be raised on a hoist, make sure it is lifted on the frame only so the front suspension is in full rebound under load.

TORSION BAR, REPLACE

1957-59

1. Raise vehicle by jacking under frame crossmember. Release load from torsion bar by unscrewing anchor adjusting bolt partly out of swivel.
2. Remove lock ring from rear of anchor. Slide torsion bar rearward to disengage forward end of bar from lower control arm. Then move forward to disengage bar from anchor. Remove bar, swivel and cam from frame bracket anchor.

Fig. 4 Torsion bar rear support. 1960

Installation

1. Assemble anchor, swivel, bolt seat (oval side up) and bolt in frame anchor bracket. Check for torsion bar cushion in lower control arm housing. With cam bolt barely entered in cam swivel, slide bar into rear cam.
2. Rotate anchor and torsion bar until anchor is positioned as close as possible to floor pan. Engage front of bar in lower control arm shaft as far as bar will go. *Unless anchor blade is in the position just described when installing bar, it will be impossible to adjust front suspension to the proper height.*
3. Center and install lock ring in rear of anchor housing. Pressure may be applied to bar to enable lock ring to be installed.
4. After lock ring is installed, tighten cam bolt until approximately one inch of threads are showing above anchor bolt swivel. *This is an approximate setting used merely as a starting point when adjusting suspension height This setting is also necessary to place load on torsion bar before lowering vehicle to floor.*

Fig. 5 Front suspension height adjustment. 1961-62

Fig. 6 Section view of upper and lower ball joints

5. Check and adjust suspension height as outlined further on.

1960-62

1. Raise vehicle by jacking under center of front crossmember.
2. Release load from torsion bar by backing off anchor adjusting bolts.
3. Remove bolt and swivel and discard.
4. Remove plastic seal from rear end of torsion bar anchor, and remove lock ring from anchor.
5. Slide torsion bar toward rear of car enough to disengage forward end from lower control arm. Slide bar forward and down, disengaging it from anchor, and remove bar.

Installation

1. Slide new anchor end seal over end of bar with cup side facing rear.
2. Install torsion bar and position seal in groove on anchor hub.
3. Turn torsion bar until anchor is positioned approximately 120° (8 o'clock position) down from frame. *If anchor end is not in this position when installing bar it will be impossible to adjust the suspension to the correct height.* Engage front of bar in hex opening in lower control arm.
4. Before installing lock ring, center bar so that full contact is obtained at anchor and control arm shaft. Install lock ring in groove.
5. Pack anchor seal with grease and position lip of seal in anchor hub groove. Install plastic seal in rear end of anchor.
6. Slide adjusting bolt swivel on frame and install adjusting bolt and seat. Tighten bolt into swivel until approximately one inch of threads are showing out of swivel. *This is an approximate setting used as a starting point when adjusting for correct suspension height. This setting is also necessary to place a load on the bar before lowering vehicle to floor.*
7. Lower car to floor and adjust suspension height as outlined below.

SUSPENSION HEIGHT, ADJUST

1. Jounce car so parts can assume normal position.
2. Measure from lower ball joint to floor and from bottom of lower control arm bushing housing to the floor.
3. Subtract one measurement from the other. The difference should be as listed below subject to a tolerance of plus or minus ⅛".

1957-58 Cars	¼"
Suburbans	2¾"
C-300 Models	1¾"
1959 Cars	2⅛"
Suburbans	2½"
1960-61 Cars	2"
Suburbans	2½"
1962 Cars	2"
Suburbans	2⅜"

If these measurements differ more than ⅛" or if one or both of them are outside the specified limits, the suspension height of both sides must be adjusted. To adjust, turn the anchor bolt clockwise to raise the height and counterclockwise to lower it, Figs. 3, 4, 5.

BALL JOINT SERVICE

1. To replace ball joints, Fig. 6, raise car by jacking under lower control arm and remove wheel assembly.
2. Remove upper and lower ball stud nuts and slide tool shown in Figs. 7 and 8 down over lower stud until it rests on steering knuckle.
3. Turn threaded portion of tool, locking it against ball joint being removed. Spread tool enough to place ball stud under pressure, then strike the steering knuckle sharply with a hammer to loosen the stud. *Do not attempt to force the stud out of the knuckle with the tool alone.*
4. Remove tool, then disengage ball joint from knuckle.
5. Remove dust cover and grease seal.
6. Remove grease fitting and unscrew ball joint from control arm.
7. When installing ball joints, it is important that the threads engage those of the control arms squarely. Torque the ball joints to the control arms to 125 ft. lbs., the lower stud nut to 135 ft. lbs., and the upper stud nut to 100 ft. lbs.

Fig. 7 Removing upper ball joint from steering knuckle

Fig. 8 Removing lower ball joint from steering knuckle

FRONT END REPAIRS, 1955-56

Shock Absorber

1. Raise hood and clean the area around the upper mounting.
2. Slide a wrench over the flats on top of the shock absorber piston rod to keep the rod from turning. Then remove the nut and cup washer.
3. Remove the two lower mounting bolts and withdraw the shock absorber through the opening in the spring seat. Lower cup washer may remain in place or drop through when shock absorber is removed.
4. Using a suitable drift, force the inner steel sleeve out of the bushing and remove the bushing from the frame opening.
5. Before installing a new bushing, dip it in soapy water and insert in the frame with a twisting motion. When installed properly, the groove in bushing will index the frame.
6. Force steel sleeve through opening in bushing and down into position.

Kingpins & Bushings

1. Remove wheel and hub assembly.
2. Block brake pedal so it cannot be depressed.
3. Unfasten brake support plate from knuckle.
4. Remove steering arm from knuckle.
5. Remove brake hose and connection and lift off brake support.

Fig. 9 Front suspension. 1955-56

6. Remove kingpin lock pin.
7. Drive a punch into upper steering knuckle welch plug and pry out plug.
8. Drive kingpin downward, forcing out lower welch plug. A soft brass drift should be used in driving against top of kingpin.
9. If needle bearings are used in the knuckle they should be removed with a suitable puller. A puller should also be used when pressed-in bushings are employed.

When installing needle bearings they must be installed from the top of the knuckle with the trade mark on top and the oil hole lined up with the oil hole in the steering knuckle.

Pressed-in type bushings must be line reamed.

After installing the steering knuckle, make sure it is free in the support as binding at this point may cause sensitive steering and car wander. There should be .008 in. clearance between the knuckle and knuckle support. This clearance can be adjusted by the use of shims between the knuckle and thrust bearing.

After their installation, welch plugs should be staked in place.

Upper Control Arm

1. With a jack under the lower control arm spring seat, raise the car and remove the wheel.
2. Remove shock absorber.
3. Unscrew bolt from outer end of control arm.
4. Unfasten and remove control arm pivot bar.

Lower Control Arm

To remove the lower control arm, raise the front end of the car off the floor and place a support under the frame side member behind the suspension unit. After removing the wheel, disconnect the shock absorber and the sway eliminator at the lower shock absorber mounting stud. Place a jack under the control arm pivot bar where it is attached to the frame cross member. Use a block of wood, Fig. 9, cut to receive the lower control arm bar between the jack and the bar, which will prevent the jack from slipping. Now raise the jack just enough to relieve the pressure on the pivot bar fastening bolts. Remove the bolts, placing tapered drifts in each hole, to prevent binding of the last bolt removed. Lower the jack slowly, allowing the lower control arm to come down, then lift out the spring. Remove the lower control arm pin from the knuckle support and take out the lower control arm assembly.

HORN SOUNDER & STEERING WHEEL

1961-62

1. Remove two screws from underside of steering wheel and remove horn ring, retainer and attaching screws.
2. Disconnect horn wire at horn switch and remove switch.
3. Loosen steering wheel nut several turns and loosen steering wheel with puller. Then remove puller, nut and wheel.

1960

1. Disconnect battery ground cable.
2. Remove steering wheel ornament by pressing down on center ornament and turning it ¼ turn to remove.
3. Disconnect horn wire and remove three screws, bushings, horn ring, rubber insulator and horn terminal plate.
4. Loosen wheel nut three turns. Then use puller to loosen wheel.
5. Remove puller, nut and wheel.

1957-59

1. Disconnect battery.
2. Turn ornament counterclockwise to remove.
3. Disconnect wire from terminal and remove three screws, three bushings and horn ring.
4. Remove horn sounding contact ring switch from wheel hub.
5. Loosen wheel nut three turns and loosen wheel with a puller.
6. Remove puller, nut and wheel.

1955-56

1. Disconnect battery.
2. Press down on horn ring ornament and turn counterclockwise.
3. Lift out ornament retaining spring and pad.
4. Disconnect horn wire from terminal on travel plate and insulator.
5. Remove bushing, travel plate, horn contact ring spring and triangular ground plate.
6. Curl and push horn wire into steering gear tube to make room for wheel puller pilot.
7. Remove wheel nut, attach puller and remove wheel.

MANUAL STEERING GEAR, REPLACE

1955-56

Note—It is not necessary to remove the steering column and mast assembly to service the lower worm bearings and cross shaft assembly.

1. Disconnect battery.
2. Press down on horn ring ornament while rotating it and remove ornament.
3. Pull off steering wheel.
4. Loosen jacket-to-instrument panel bolts.
5. Remove dust pad retaining screws.
6. Remove pitman arm.
7. Loosen jacket - to - gear housing clamp bolt.
8. Remove housing-to-frame attaching bolts and work gear and cross shaft out of jacket.
9. Remove assembly from lower side of car.

1957-59 & Early 1960 Windsor

Note—It is not necessary to remove the steering column and mast assembly to service the lower worm bearings and cross shaft assembly.

1. Disconnect battery ground cable.
2. Remove steering wheel and disconnect horn and turn signal wires at instrument panel. On 1960, remove turn signal switch from jacket tube.
3. Remove jacket tube clamp at steering gear housing.
4. Remove jacket support clamp at instrument panel.
5. Remove dust shield at firewall.
6. Remove floor opening panel.
7. Remove pitman arm.
8. Remove steering gear housing-to-frame bolts.
9. Slide jacket tube and remove control units rearward through the driver's compartment as an assembly.
10. Remove brake pedal pad.
11. Remove gear from engine side of firewall.

Late 1960 Windsor & All 1961-62

1. Pull off steering gear arm.
2. Remove bolt which fastens coupling to worm shaft.
3. Unfasten steering gear from frame (3 bolts) and slide gear forward to disconnect coupling from worm shaft.
4. Mark the index (master serration) position with chalk on outside of coupling hub. Then raise gear and remove it from engine compartment.

Installation

1. Locate steering gear center by rotating worm shaft from one extreme to the other while counting the number of turns. Then turn the worm shaft back ½ the number of turns, which is the exact center of steering gear travel.
2. Locate master serration in outer row of serrations on worm shaft. Mark master serration and index the gear into the engine compartment.
3. Align index mark on outside of coupling hub with master serration on worm shaft.
4. Slide coupling on worm shaft and fasten gear housing to frame, tightening bolts evenly to a torque of 50 ft. lbs.
5. Position coupling bolt hole in line with groove on worm shaft and install bolt and lockwasher; tighten bolt to 30-35 ft. lbs. *It is important that the steering tube be centered in the steering column seal and that the lip of the seal that contacts the steering tube be well lubricated with wheel bearing grease at 5000 mile intervals.*

Fig. 10 Manual steering gear. 1961-62

POWER STEERING

Replace, 1955-56

1. Remove horn ring ornament by pressing it down and turning. Disconnect wire and remove horn ring.
2. Remove steering wheel, turn signal lever and plate.
3. Loosen steering column - to - instrument panel bracket.
4. Loosen steering column jacket clamp screws.
5. Remove floor mat retaining plate and rubber dust pad.
6. Remove pitman arm.
7. Loosen housing-to-frame attaching bolts.
8. Disconnect pressure and return hoses.
9. Fasten disconnected ends of hoses above oil level in reservoir to prevent further loss of oil. Cap ends of hoses to prevent the entrance of dirt.
10. Remove gear housing-to-frame attaching bolts and alignment wedge.
11. Remove gear assembly from under side of car.

Replace, 1957

1. Remove steering wheel and power steering column jacket.
2. Remove pin and disconnect steering tube from coupling.
3. Remove floor mat retaining plate.
4. Remove rubber dust pad and floor pan opening cover.
5. Remove pitman arm.
6. Loosen gear housing-to-frame attaching bolts.
7. Disconnect pressure and return hoses.
8. Cap fittings at steering gear and fasten disconnected ends of hoses above oil level in reservoir to prevent further loss of oil. Cap ends of hoses to prevent entrance of dirt.
9. Disconnect stop light switch wires from brake master cylinder.
10. Disconnect brake booster reservoir from fender side shield and move aside.
11. Remove gear housing-to-frame attaching bolts and alignment wedge.
12. Remove gear assembly by sliding unit forward and out of engine compartment.

Replace, 1958-62

1. Disconnect battery ground cable.
2. Disconnect horn wire.
3. Remove horn button and horn ring and disconnect horn wire.
4. Remove steering wheel.
5. Disconnect turn signal wires at connectors and on 1960-61 models, remove turn signal switch. Also on 1960-61 models, remove retainer snap ring from the groove in the steering tube at the top of the bearing.
6. Remove jacket tube support bracket at instrument panel. Loosen two bolts attaching jacket tube to steering housing, push jacket tube upward to expose the steering tube coupling pin and remove the pin.
7. Disconnect pressure and return hoses at steering gear. Fasten disconnected ends of hoses above oil level in reservoir. Cap ends of hoses and fittings on steering gear to prevent the entrance of dirt.
8. Use puller to remove steering arm. Unfasten and remove steering gear from frame and out through engine compartment.
9. On cars with Ram Manifold, remove the fender opening panel. Raise lower end of gear housing and rotate the assembly in a clockwise motion towards the cowl panel until the gear shaft splines clear the frame rail, then tilt the housing toward the engine and remove the gear through inspection hole at fender side panel.
10. Reverse removal procedure to install gear.

MANUAL STEERING GEAR REPAIRS

1955-62

In this type steering gear, Fig. 10, the worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth roller is attached to the roller shaft by means of a steel shaft. Two needle bearing assemblies are installed between this shaft and the roller. (Some light duty models have a two tooth roller shaft).

The roller shaft is mounted in the steering gear housing on two needle bearing assemblies which are pressed into the housing. The housing cover is attached to the housing by four cap screws. An adjustment screw, mounted

in the cover, controls roller shaft end play and worm and roller mesh adjustment.

The steering wheel and roller shaft arm (pitman arm) are splined to the steering shaft and roller shaft respectively. Both the pitman arm and steering wheel have master splines to insure correct installation.

Worm End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the four cover screws about 1/8".
3. Use a knife to separate the top shim, passing the blade all the way around between the shims, being careful not to damage the remaining shims.
4. Remove one shim at a time between inspections to remove the end play.
5. The adjustment is correct when there is no end play and no stiffness in the steering gear throughout the complete range of its travel.

Roller Shaft End Play, Adjust

1. Turn the steering gear to either extreme and back off 1/8 of a turn.
2. Gripping the pitman arm at the hub, the roller shaft should rotate freely without a particle of end play.
3. If end play exists, adjust as required by means of the roller shaft adjusting screw in the side cover.
4. Be sure to tighten the lock nut securely and inspect for end play and free rotation throughout the entire range of steering gear travel.

Worm & Roller Mesh, Adjust

1. Loosen the roller shaft adjusting screw lock nut.
2. With the steering gear in its central position (drag link disconnected) tighten the roller shaft adjusting screw just enough to remove play between the roller shaft roller tooth and worm.
3. Check this by the amount of play felt at the pitman arm. It is better to leave a slight amount of play at this point than to tighten too much.
4. If tightened beyond the point where the lash is removed, serious results will occur which will cause poor steering operation.
5. Tighten the adjusting screw lock nut.

Radio, Speedometer and Windshield Wiper

WINDSHIELD WIPER

1955-56 Chrysler & Imperial

Due to the restricted room properly to assemble the eccentrics at the crank arm link ends, it will be necessary to remove the wiper assembly as a unit whenever the wiper or links are to be serviced.

Before attempting to remove the wiper motor for complete disassembly, the wiper should be operated and then shut off by turning off the ignition. *Failure to observe this precaution will result in irreparable damage to the motor switch and spring parking cam when the switch cover is removed.*

To remove the wiper, proceed as follows:

1. Disconnect wiper motor.
2. Remove right-hand fresh air door.
3. Remove clips that hold links to pivot cranks. *Clips are removed by lifting top tab and sliding sideways out of engagement with groove in pivot crank pin.*
4. Remove brass spacing washer.
5. Slip end of link containing nylon ball bushing off pivot crank pin.
6. Remove three retaining nuts and remove wiper motor bracket and links. A thick rubber gasket is assembled between motor bracket and dash panel to reduce noise.
7. Reverse the above procedure to install the wiper assembly.
8. Adjust parking position if necessary by moving the cam adjustment lever which sticks out of the switch cover.
9. Connect wires from motor to switch as follows:
   Blue wire to "P" terminal.
   Black wire to "A" terminal.
   Red wire to "F1" terminal.
   Yellow wire to "F2" terminal.
   Hot lead wire (red) from fuel gauge is attached to circuit breaker.

1957-59 Chrysler & Imperial

To facilitate assembly and disassembly of eccentrics at the motor crank and link ends, the wiper assembly should be removed as a unit whenever wiper or links are to be serviced.

To remove the wiper on cars *not* equipped with heater and refroster ducts, first disconnect the wiper leads at the switch. Disconnect wiper links at pivot cranks by removing clips and brass washer. Remove 3 nuts which hold large motor bracket to firewall. The complete unit may now be removed by moving the bracket back far enough to clear the studs and lowering unit down under instrument panel. *Care should be taken not to bend the links, and the battery should be disconnected to eliminate the possibility of shorts.*

To remove the wiper on cars *equipped* with heater and defroster ducts, first remove glove box and door. If car is equipped with a radio that removes from front of instrument panel, time will be saved by removing it. Disconnect wiper leads from switch. Disconnect links from pivot cranks. While holding unit in place, remove 4 self-tapping studs from motor plate to motor bracket which is attached to firewall. The unit may now be moved horizontally towards passenger side and then down from under instrument panel.

Installation is accomplished in the reverse order of removal. To readjust wiper arms, loosen wiper arm nut until a definite click is heard. Move arm to desired position and tighten. Connect the wires from the motor to the switch controls as follows:
Red wire to "F1" terminal.
Yellow wire to "F2" terminal.
Black wire to "A" terminal.
Blue wire to "P" terminal.
Hot lead from battery to circuit breaker.

1955-59 De Soto

The wiper motor should be operated and shut off by turning off the ignition. The motor must not be disassembled when the cranks are in the parked position or damage to the motor switch and contact follower will occur when the cover is removed. To remove the wiper, proceed as follows:

1. Disconnect wires at motor.
2. Remove radio and right-hand fresh air door.
3. Disconnect links at pivot cranks. Clips are removed by lifting the top tab and sliding it sideways out of engagement with the groove in pivot crank pin.
4. Remove spacing washer and remove link from pivot crank.
5. Disconnect mounting bracket at dash panel and remove wiper motor and bracket.
6. Reverse procedure to install, being sure rubber mounting gasket is in place.
7. Adjust wiper parking position by moving cam adjustment lever which projects from switch cover.

1960-62

1. Remove glove compartment door.
2. Remove glove compartment.
3. Remove bolts attaching wiper motor bracket to the cowl panel to the instrument panel brace.
4. Disconnect wires at wiper motor.
5. Disconnect links at the pivot cranks. Clips are removed by lifting the top tab and sliding it sideways out of engagement with the groove in the pivot crank pin.
6. Remove the spacing washer and remove the link from the pivot crank.
7. Slide the complete wiper with the links far enough towards the left so the right hand link will clear the glove compartment opening in instrument panel and remove assembly using care so as not to bend the links.

RADIO REPLACE

1955-56 De Soto

The radio panel must first be removed from the front of the instrument panel

to gain access to the radio.

On 1956 cars equipped with cigar lighter in the ash receptacle, remove the lead wire from the junction blocks at the left support bracket.

1955-56 Chrysler & Imperial

1. Remove ash tray and cowl vent plate.
2. Remove cowl vent lever knob and cowl vent mechanism.
3. Swivel cowl vent tube back for clearance.
4. Disconnect radio and speaker lead wire.
5. Remove control knobs and mounting nuts.
6. Remove radio and speaker.
7. To install, reverse removal procedure. Adjust antenna compensator after radio is installed, being sure antenna is fully extended.

1957 Chrysler & Imperial

1. Disconnect antenna, pilot lamp lead from orange wire on harness, two wire lead from speaker, "A" lead from accessory terminal on temperature gauge.
2. Remove rear speaker wire plug.
3. Remove mounting screw from lower instrument panel-to-bracket on radio.
4. Remove radio and ash receiver housing from panel (Chrysler only).
5. Remove radio and speaker from underneath instrument panel.
6. To install, reverse removal procedure. *Do not operate radio with speaker disconnected from radio. Insert jumper wire in rear seat speaker socket, otherwise receiver will not operate.*

1957-58 De Soto

Disconnect battery ground cable and "A" lead wire at temperature gauge. On Electro-Touch Tuner models, disconnect power unit connecting plug. Disconnect speaker wires. Remove radio mounting screws on front of radio and nuts from mounting studs.

1958 Chrysler

1. Remove speaker grille and speaker.
2. Disconnect "A" lead, pilot lamp and rear seat speaker plug.
3. Remove mounting screw from lower instrument panel to bracket on radio.
4. Remove nuts from studs on rear of radio and ash receiver housing.
5. Remove two screws from bottom of radio and ash receiver housing.
6. Remove radio and ash receiver housing with radio attached from front of instrument panel.
7. Reverse above procedure to install radio. *Do not operate radio with speaker detached or damage to transistor will result. If rear seat speaker is disconnected, insert jumper wire in rear seat speaker socket, otherwise receiver will not operate.*

1958 Imperial

1. Disconnect antenna, pilot lamp lead from orange wire on harness.
2. Remove speaker grille and speaker.
3. Disconnect "A" lead from accessory terminal on temperature gauge.
4. Remove rear seat speaker wire plug.
5. Remove radio mounting nut.
6. Remove radio control knobs.
7. Remove radio from underneath instrument panel.
8. Reverse above procedure to install.

1959 De Soto

1. Disconnect battery cable.
2. Remove speaker and defroster grille.
3. Disconnect speaker leads and "A" lead wire at fuse.
4. Disconnect antenna lead and remove air deflector from distribution duct.
5. Remove screw and washer assembly from instrument panel brace-to-radio mounting bracket.
6. Remove radio knobs and nuts, and lower radio from rear of instrument panel.
7. When reinstalling radio, be sure pilot lights are firmly in place and lead wires are not pinched in any way.

1959 Chrysler

1. Remove vent deflector at heater housing.
2. Disconnect antenna, rear seat speaker plug. "A" lead to the radio terminal of fuse block and dial lamp lead to orange wire at harness.
3. Remove clutch nut and screw from radio support bracket.
4. Remove control knobs.
5. Unfasten radio from panel (2 nuts) and remove radio and mounting bracket from underneath instrument panel.
6. Remove speaker from grille.
7. Remove grille if necessary.

Precaution

Do not operate radio with speaker detached, since damage to the transistor will result. If the rear seat speaker is disconnected from the radio, insert a jumper wire in rear seat speaker socket or the receiver will not operate.

1959 Imperial

1. Disconnect antenna, and the dial lamp lead from the orange lead of harness.
2. Disconnect the two-wire lead from speaker.
3. Disconnect "A" lead from radio terminal at fuse block.
4. Remove rear seat speaker wire plug.
5. Remove mounting nut from lower instrument panel-to-bracket on radio.
6. Remove radio control knobs.
7. Remove radio from underneath instrument panel.
8. Remove speaker.

1960-61 De Soto

1. Disconnect battery.
2. Disconnect antenna "A" lead, light lead and speaker leads.
3. Remove ash tray assembly to gain access to mounting bolts.
4. Remove mounting bolts and both radio-to-dash support brackets.
5. Remove radio assembly from under instrument panel.

1960-62 Chrysler

1. Disconnect battery.
2. Remove control knobs and shaft mounting bolts.
3. Remove radio-to-dash support brackets.
4. Disconnect "A" lead, light lead, speaker leads, antenna lead and foot selector switch, if so equipped.
5. On models with air conditioning, remove speaker attaching screws and grille from top side of instrument panel and remove speaker and radio assembly up through opening of instrument panel.
6. On models without air conditioning, remove radio from bottom of instrument panel.

1960-62 Imperial

1. Disconnect battery.
2. Remove radio-to-dash support bracket.
3. Remove two screws attaching fuse block to instrument panel and lower the fuse block.
4. Disconnect "A" lead, light lead, speaker leads, antenna leads and foot selector switch connector, if so equipped.
5. Remove radio assembly from bottom of instrument panel.

Precaution

Do not operate radio with speaker detached, since damage to transistors may result. If rear seat speaker is disconnected from the radio, insert a jumper wire in rear speaker socker to allow receiver to operate.

SPEEDOMETER REMOVAL

1955-59 Chrysler

Disconnect battery and speedometer cable housing. Remove two nuts from rear of panel and slide speedometer out through front of instrument panel.

1957-59 Imperial

Disconnect the battery cable and remove the knob on the parking brake release handle. Disconnect the parking brake cable at the pedal assembly, then remove the assembly by working it out of the instrument panel and dash panel. Disconnect the speedometer cable and the trip mileage reset cable, and pull out the speedometer light sockets. Move the wiring harness out of the way and remove the speedometer attaching nuts. The speedometer can then be taken out by working it to the left of the steering column.

1955-56 De Soto

1. Disconnect battery.
2. Disconnect speedometer cable housing.
3. Remove three speedometer to panel attaching screws in back of panel.
4. Remove speedometer assembly from behind the dash.

1957-58 De Soto

1. Disconnect battery cable.

2. Disconnect speedometer cable housing.
3. Remove switches from speedometer bezel without disconnecting the wires. This can be done by pushing them through their mounting holes into the dash panel.
4. Remove the speedometer bezel attaching screws which are accessible from the face of the dash.
5. Move speedometer out of dash toward steering wheel.

1959 De Soto

1. Disconnect battery.
2. Disconnect speedometer cable housing.
3. Remove speedometer bezel attaching screws which are accessible through the face of the dash.
4. Move speedometer out of dash toward steering wheel.

1960-61 De Soto

1. Disconnect the battery cable.
2. Disconnect speedometer cable at speedometer.
3. Remove transmission push button bezel.
4. Remove transmission control push buttons.
5. Remove the two retainer stud nuts that hold the transmission push button housing assembly to dash, then remove housing and disconnect back-up light wires. Move housing out of way.
6. Disconnect the three instrument panel lights.
7. Remove steering column dash support to cowl panel brace.
8. Disconnect horn and turn signal wires at the connector under dash.
9. Remove four screws that attach speedometer to instrument panel. *Hold speedometer while removing last screw, to avoid possibility of dropping and scratching the lens.*
10. When screws are removed, tilt speedometer base toward firewall and carefully lower the speedometer until the lens has cleared the instrument panel opening. Move speedometer in direction of parking brake and at same time roll the end toward the parking brake, downward, until the speedometer lens is straight up and down. Turn speedometer 180° until the base is toward the firewall, and lower speedometer to remove.

1960-62 Chrysler

1. Disconnect battery ground cable.
2. Remove steering wheel.
3. Remove steering jacket tube cover from underside of jacket tube.
4. Disconnect all wires at terminals before loosening instrument cluster attaching screws.
5. Disconnect instrument ground wire.
6. Remove instrument cluster bezel (2 nuts).
7. Disconnect speedometer cable.
8. Remove steering tube collar (2 screws).
9. Detach dome and cluster from dome support by removing two long screws and spacers located just behind steering tube collar attaching screws.
10. Detach plastic dome from instrument panel (4 screws).
11. Carefully release base of dome from supports at each side with a pointed instrument. Move dome away from opening in panel so that top of dome and cluster can be tipped outward far enough to gain access to the parking brake warning light socket. *In some cases where dome fits tightly in support it may be necessary to remove six screws that attach cluster to dome. Push cluster up into dome and carefully compress dome to clear supports on removal.*
12. Snap out lamp socket and bulb and remove dome and cluster from car.
13. Remove speedometer (4 screws).
14. Reverse removal procedure to install.

1960-61 Imperial

1. Disconnect battery ground cable.
2. Remove chrome retainer ring retaining screw at bottom of retainer.
3. Pull the bottom of the retainer forward and raise the retainer to release the upper tab located at top of retainer.
4. Remove speedometer cable, unfasten and remove speedometer.

1962 Imperial

1. Disconnect battery ground cable. *If equipped with heater and/or air conditioning, it will be necessary to remove defroster and spot cooler hoses.*
2. Disconnect speedometer cable.
3. Disconnect odometer reset cable at instrument panel cluster.
4. Unfasten (5 screws) and remove instrument cluster by tilting lower edge of cluster outward.
5. For speedometer or complete cluster removal, disconnect all electrical connections, and disengage wire harness loom from clips.

Engine Section

ENGINE, REPLACE

1. Drain cooling system and oil pan.
2. Remove hood, air cleaner, radiator, fan and pulley, and starter.
3. Disconnect usual items such as wires, fuel and vacuum lines, carburetor linkage, etc.
4. Cars with standard transmission, disconnect clutch retracting spring. Then remove clutch equalizer shaft arm bracket at underbody rail.
5. Raise car. Remove flywheel or converter housing upper retaining bolts through access holes in floor pan.
6. Disconnect exhaust pipe at exhaust manifold.
7. Disconnect engine right and left mounts at underbody bracket.
8. Remove flywheel or converter housing cover.
9. Cars with standard transmission, remove flywheel housing lower retaining bolts.
10. Cars with automatic transmission, disconnect converter from flywheel and remove converter housing retaining bolts.
11. Lower car. Support transmission and flywheel or converter housing with a jack.
12. Attach engine lifting rig and lift engine from chassis.
13. Reverse above procedure to install the engine.

Comet and Falcon engine

CYLINDER HEAD, REPLACE

1. Drain cooling system, remove air cleaner and disconnect battery cable at cylinder head.
2. Disconnect exhaust pipe at exhaust manifold.
3. Disconnect carburetor linkage, fuel and vacuum lines, water hoses and wires from spark plugs.
4. Remove rocker arm cover.
5. Back off valve adjusting screws to remove load from rocker arms. Then remove rocker arm shaft assembly.
6. Remove valve push rods, keeping them in proper sequence so they are returned to proper locations.
7. Remove one bolt from each end of cylinder head at opposite corners and install cylinder head guide studs ($\frac{7}{16}$"-14 x 6").
8. Remove remaining bolts and lift off cylinder head.
9. Reverse above procedure to install the cylinder head and tighten bolts in the sequence shown in Fig. 1 to the torque given in the *Engine Tightening Chart.*

VALVE ARRANGEMENT

Front to rear . . E-I-I-E-I-E-E-I-E-I-I-E

Fig. 1 Cylinder head bolt tightening sequence

VALVES ADJUST

Before the final valve lash adjustment is made, operate the engine for 30 minutes at a fast idle to stabilize engine temperatures. To set the lash accurately, use only a step-type feeler gauge. For example, to obtain the correct setting if the clearance is .016", the .015" portion of the gauge ("go") should enter but the "no go" end (.017") should not enter.

Before starting the adjustment procedure, make two chalk marks on the crankshaft pulley. Space the marks approximately 120° apart (⅓ of circumference) so that with the timing mark the pulley is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

VALVES REMOVE

After taking off the head as outlined previously, proceed as follows:

1. Remove capscrews retaining rocker shaft brackets to head and remove shaft assembly.
2. Clean carbon out of combustion chambers before removing valves.
3. Compress valve springs with a suitable spring compressor, remove valve stem locks and release the springs. Remove sleeve, valve spring cap retainer, spring and valve. Discard intake valve seals, Fig. 2.
4. Place valves in a board with numbered holes so they can be replaced in their original positions upon reassembly.

Fig. 2 Valve assembly

VALVES GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$", otherwise the valve must be replaced.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

VALVE GUIDES

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guides can be reamed oversize to accommodate one of three service valves with oversize stems (.003", .015" and .030").

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004" on the intake or .005" on the exhaust, ream the valve guides to accommodate the next oversize diameter valve.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 3. If the assembled height is greater than the dimension given in the *Valve Specifications Chart*, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 3 Checking installed height of valve spring

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

Fig. 4 Checking valve spring pressure

Fig. 5 Rocker arm shaft assembly

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 4, and according to the specifications given in the *Valve Data Chart*. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

ROCKER ARMS REPLACE

1. To disassemble, remove pin and spring washer from each end of rocker shaft, Fig. 5.
2. Slide rocker arms, springs and supports off the shaft, being sure to identify location of parts for reassembly.
3. If it is necessary to remove the plugs from the shaft ends, drill or pierce the plug on one end. Then use a steel rod to knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Assemble

1. Lubricate all parts with engine oil. Apply Lubriplate to the rocker arm pads.
2. If plugs were removed from shaft ends, use a blunt tool or large diameter pin punch and install a plug (cup side out) in each end of shaft.
3. Install spring washer and pin on one end of shaft.
4. Install rocker arms, supports and springs in order shown in Fig. 5. *Be sure oil holes in shaft are facing downward.*
5. Complete the assembly by installing remaining spring washer and pin.

VALVE LIFTERS, REPLACE

When necessary to replace the lifters, remove the cylinder head and related parts as outlined previously. Using a magnet, remove and install one lifter at a time, Fig. 6.

When installing, apply Lubriplate to each lifter foot and coat the remainder of the lifter with engine oil before installation.

TIMING CASE COVER

1. To remove cover, drain cooling system.
2. Remove radiator, fan and pulley, and crankshaft pulley.
3. Remove cover and gasket (crankcase ventilation tube bracket is retained by one cover bolt).
4. *If oil pan gasket is broken or damaged during front cover removal, drop the oil pan and install a new gasket.*
5. To replace the cover oil seal, drive out the seal with a pin punch and clean out the recess. Coat a new seal with grease and install the seal, driving it in until it is fully seated in cover recess. Check the seal after installation to make sure the spring is properly positioned in the seal.

Fig. 6 Removing valve lifter using magnetic rod

Fig. 7 Timing marks lined up for correct valve timing

TIMING CHAIN

After removing the cover as outlined above, remove the crankshaft front oil slinger. Crank the engine until the timing marks are aligned as shown in Fig. 7. Remove camshaft sprocket retaining bolt and washer. Slide both sprockets and chain forward and remove them as an assembly.

Reverse the order of the foregoing procedure to install the chain and sprockets, being sure the timing marks are aligned.

Fig. 8 Camshaft and related parts

CAMSHAFT REPLACE

To remove camshaft, remove cylinder head and related parts, radiator, oil pan, timing chain cover and valve lifters.

Remove timing chain and sprockets, camshaft thrust plate, and pull camshaft out of engine. If thrust plate shows signs of wear, install a new one.

CAMSHAFT BEARINGS REPLACE

To install new bearings it will be necessary to remove the engine from the car. The bearings are available pre-finished to size and require no reaming for standard and .015″ undersize journal diameters. Number 4 bearing is not interchangeable with the other bearings.

1. After removing the engine, remove the camshaft and rear bearing bore plug.
2. Remove camshaft bearings, Fig. 8.
3. To install, position the bearing at the bearing bore and press it in place. *No. 1 bearing must be pressed in .100-.140″ below front face of bearing bore. Press the remaining bearings in sufficiently to align the oil supply holes.*
4. Clean camshaft rear bearing bore plug recess and install a new plug.
5. Install parts removed and install engine in car.

PISTONS & RODS REMOVE

After removing the cylinder head and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

PISTON & ROD ASSEMBLE

When installed, piston and rod assembly should have the notch in piston head toward front of engine with oil squirt hole in rod positioned as shown in Fig. 9.

PISTONS

Pistons are available for service replacement in standard sizes and oversizes of .020″, .030″, .040″ and .060″.

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an oil piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

New pistons should be fitted according to the recommendations given in Fig. 10.

PISTON PINS

The piston pin bore of the connecting rod must be within the limits of .9107-.9112″. The diameter of the piston pin must be within the limits of .9120-.9123″.

Apply a light coat of engine oil to all parts. Assemble the piston to the connecting rod as shown in Fig. 9. Start the piston pin in the piston and connecting rod. Use the equipment shown in Fig. 11 and draw the pin through the piston and rod until end of pin seats in Detail 2, Fig. 11. If this equipment is not available, the pin may be installed with a suitable press.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cyilnder in which it will be used. Square it in bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bear-

Fig. 9 Piston and rod assembly

Fig. 10 Piston clearance chart

ing, Fig. 12. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

Fig. 12 Checking rod bearing clearance with Plastigage

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell, Fig. 13.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding end of the seal with sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced, it is possible to do the job without removing the crankshaft as follows:

To remove the old seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being moved.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is being installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direc-

Fig. 11 Piston pin installation

Fig. 13 Crankshaft and related parts

tion of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN REPLACE

1960-62 Falcon

1. On car with manual shift transmission, remove clutch retracting spring.
2. Remove crossmember.
3. Unfasten stabilizer bar from underbody and pull stabilizer bar downward.
4. Remove oil pan bolts and crank engine as required to obtain clearance and remove oil pan.

1960-62 Comet

1. To remove, drain oil and remove dipstick.
2. Remove front engine mounting nuts and raise front of engine with a jack and a wood block placed under the oil pan.
3. Position 2-inch wood blocks between each engine front support and support bracket and lower engine on blocks.
4. Remove stabilizer bar-to-underbody nuts and pull stabilizer bar downward.
5. Remove oil pan retaining bolts and crank engine as required to obtain clearance for removal of pan.
6. Reverse above procedure to install.

OIL PUMP REPLACE

1. Remove oil pan as directed above.
2. Remove pump pick-up tube and screen.
3. Unfasten and remove pump from engine.
4. Reverse order of removal to install.

OIL PUMP REPAIRS

Referring to Fig 14, disassemble pump. To remove the oil pressure relief valve, insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber cap and

Fig. 14 Oil pump assembly

pull cap out of chamber. Remove spring and plunger.

The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.

Install the pump cover and tighten to 6-9 ft. lbs. torque.

RADIATOR

Drain cooling system and disconnect upper and lower hoses at radiator. If equipped with oil cooler, disconnect lines from lower tank. Unfasten radiator from its support and lift out radiator.

WATER PUMP REPLACE

Drain cooling system and remove lower hose at water pump. Remove drive belt, fan and water pump pulley. Disconnect heater hose at water pump. Unfasten and remove water pump.

WATER PUMP REPAIRS

To disassemble pump, refer to Fig. 15 and remove hub from impeller shaft. Press shaft and bearing out of housing. Remove impeller from shaft.

To assemble, clean all gasket material from pump. If a new shaft is used, install the slinger on the shaft in the same relative position as the old slinger. Coat the bearing outer diameter with grease and press the shaft into the housing. Apply a light film of waterproof sealer on a new seal and press seal into housing. Install impeller. Lightly coat seal rubbing face of impeller with grease, then press shaft onto impeller.

Press shaft into impeller just far enough so that pump housing lightly touches face of adapter ring. The impeller-to-pump body clearance should be .005-.025" after impeller is installed.

Press water pump onto shaft until there is $3\frac{15}{16}$" from gasket surface to outside surface of pump hub.

DISTRIBUTOR REPLACE

1. To remove the distributor, disconnect the primary wire and vacuum control pipe.
2. Remove distributor cap.
3. Scribe a mark on the distributor body indicating the position of the rotor, and scribe another mark on the body and engine block indicating position of distributor body in block. These marks can be used as guides when installing distributor in a correctly timed engine.
4. Remove hold down screw or screws

Fig. 15 Water pump assembly

and lift distributor out of block. *Do not crank engine while distributor is removed or the initial timing operation will have to be performed.*

Installation

If the crankshaft has not been disturbed, install the distributor, using the scribed marks previously made on the distributor body and engine block as guides.

If the crankshaft has been rotated while the distributor was removed from the engine, it will be necessary to retime the engine. Crank the engine to bring No. 1 piston on top dead center of its compression stroke. Align the timing mark on the crankshaft pulley with the timing pointer (see *Tune Up* chart). Install the distributor so that the rotor points to the No. 1 spark plug wire terminal in the distributor cap.

Make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is properly engaged, in order to engage the oil pump intermediate shaft.

IGNITION TIMING

Align the distributor rotor with No. 1 spark plug wire terminal in the distributor cap, when No. 1 piston is on the compression stroke and timing mark on the crankshaft pulley and pointer are aligned (see *Tune Up* chart).

With the timing mark in line with the pointer, the distributor points should just start to open. It may be necessary to rotate the distributor body clockwise slightly and then counter-clockwise until the points just start to open. Tighten the distributor lock plate screw.

Start the engine and check the timing with a timing light.

Using Timing Light

Connect the timing light wires. Clean the dirt from the timing mark and if necessary use white chalk or paint to make the mark more visible.

Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark do not line up as the light flashes, rotate the distributor as required to bring them in alignment.

STARTER REPLACE

Disconnect cable at starter. Unfasten and remove starter and rubber dust ring.

When installing the starter on a car with automatic transmission, the transmission dipstick tube bracket is mounted under the starter side mounting bolt. Snug all bolts, then tighten them starting from the middle bolt.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasket surfaces. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A stuck valve in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. The move the valve up and down a few times to work in the oil. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

HOLLEY CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

Year	Model	Carb. Type	Idle Adjustments★			Float Level	Fuel Level	Choke Unloader	Choke Setting
			Mixture Screw Turns Open	Fast Idle Speed	Anti-Stall Dashpot Plunger Clearance

HOLLEY NOTES

Fig. ①—Float level measured from roof of float chamber to lowest point of float with carburetor inverted.

Fig. ②—Fuel level measured from power valve mounting surface.

③—With engine running at hot idle speed, hold throttle closed and depress dashpot plunger fully. Then turn adjusting screw as required to obtain the specified clearance.

④—With hot idle properly adjusted, and with fast idle screw on lowest step of fast idle cam, adjust fast idle screw to obtain RPM listed.

⑤—With throttle wide open, clearance between upper edge of choke valve and inner wall of air horn should be as listed. Adjust by bending unloader lever on throttle shaft lever or choke fast idle link.

⑥—Measured from top of float to air horn with carburetor inverted. To adjust, bend tab on float arm.

⑦—Loosen lock nut and screw dashpot in or away from throttle operating lever. Hold throttle closed. Bottom plunger with screwdriver. Then screw dashpot in toward throttle lever until clearance between lever and tip of plunger is as specified.

Clutch & Transmission Section

CLUTCH

Pedal Adjustment

Adjust the clutch pedal whenever the clutch does not disengage or engage properly, or when new clutch parts are installed. Both the total travel and free travel of the pedal should be adjusted.

1. To check pedal assist spring tension, measure the distance between the end of the assist spring retainer and the rear surface of the pedal support, Fig. 1. This distance should be $1\frac{3}{16}$".
2. The total travel of the pedal should be 6 to 6½". If the travel is less than required, move the clutch pedal bumper and bracket until the travel is within limits.
3. Pedal free travel should be ⅞" to 1⅛". Depress the pedal slowly until the clutch release fingers contact the release bearing and note the amount of travel. If not within specifications, loosen the equalizer rod nuts. Move the equalizer bar as required and tighten the nuts. *Both nuts must be tightened against the trunnion after the adjustment is made.*

Clutch Replace

1. Remove starter and rubber dust ring.
2. Remove propeller shaft.
3. Disconnect speedometer cable.
4. Remove transmission support bolts.
5. Remove exhaust pipe bracket bolt.
6. Disconnect shift rods at transmission levers.
7. Raise engine slightly with jack and wood block under oil pan.
8. Remove transmission-to-flywheel bolts and slide transmission back and allow it to rest on cross member.
9. Disconnect retracting spring and disconnect pedal-to-equalizer rod from equalizer bar.
10. Remove hub and release bearing.
11. Remove flywheel housing and dust cover.
12. Remove clutch from flywheel.
13. Reverse above procedure to install clutch and adjust pedal travel.

STD. TRANSMISSION

Transmission Replace

1. Remove propeller shaft.
2. Disconnect speedometer cable.
3. Disconnect gearshift rods from levers at transmission.
4. Remove bolt securing extension housing to rear support, and remove bolt from exhaust pipe bracket.
5. Place jack under flywheel housing and raise engine slightly.
6. Remove four transmission mounting bolts and thread two guide studs into the two lower bolt holes.
7. Move transmission back and out of chassis.
8. Reverse above procedure to install.

Transmission Repairs

1. Referring to Fig. 2, drain lubricant

and remove cover.

2. Remove extension housing. *To prevent mainshaft from following the housing (with resultant loss of needle bearings) tap end of mainshaft with soft hammer while withdrawing housing.*
3. Remove speedometer drive gear, snap ring and drive ball from mainshaft.
4. Remove idler and countershaft retainer, tapping ends of both shafts if necessary to free retainer.
5. Using a suitable arbor, drive countershaft out of cluster gear and transmission case, leaving arbor in gear. Then lower cluster gear to bottom of case.
6. After removing bearing retainer and gasket, remove main drive gear and front synchronizer blocking ring from case.
7. Remove snychronizer snap ring from mainshaft. Then, while holding synchronizer parts together, pull mainshaft out of case. Remove mainshaft parts and two shift forks. *For reference in assembly, notice which synchronizer hub faces forward.*
8. Using a soft drift, drive reverse idler shaft out of transmission case and lift out idler gear, shaft and cluster gear out of case.
9. If necessary to remove shift mechanism, first remove the shift levers. Then from the underside of the case, drive out the tapered pins that hold the cam and shaft assemblies in the case. Drive out the cam and shafts and remove the plunger.
10. Remove shift lever oil seals.
11. Remove retaining snap ring and press main drive gear shaft out of bearing and oil slinger.
12. Remove retaining snap ring and press mainshaft out of rear bearing.
13. Reverse above procedure to assemble the transmission, referring to Fig. 2.

Gearshift Linkage Adjust

If the transmission shifts hard or if it will not engage, the gearshift levers may need adjustment at the cross-over. Move the shift lever through all positions to see that the cross-over operation is smooth. If not, adjust as follows:

1. With selector lever in neutral, remove cotter pins and flat washers from the connecting rod adjustment sleeves and pull sleeves out of levers.
2. Loosen locknut on each sleeve and then slide sleeves up or down on the rods until smooth cross-over operation results when sleeves are attached to levers. Tighten both locknuts securely.
3. Position adjustment sleeves in shift levers and install flat washers and cotter pins.

AUTOMATIC TRANS.

For detailed repair procedure and maintenance requirements on this transmission, refer to the *Two-Speed Fordomatic* section of this manual. The following outlines the procedure for adjusting the transmission linkage and the removal of the transmission from the car.

Fig. 1 Typical clutch mounting and linkage

MANUALLY-CONTROLLED THROTTLE LINKAGE

1960 and Early 1961

1. Apply parking brake and place selector lever in neutral.
2. Run engine at a fast idle until normal operating temperature is reached. When warm, slow engine down to normal idle speed.
3. Connect tachometer to engine and adjust idle speed to 475-500 rpm with selector lever in "D".
4. Check anti-stall dashpot plunger

Fig. 3 Manually-controlled throttle linkage. 1960 and early 1961

Fig. 2 Exploded view of standard transmission

clearance as given in the *Carburetor Section.*

5. With engine stopped, disconnect throttle control rod at its clevis end, Fig. 3. Loosen clevis locknut.
6. Push throttle control rod downward to hold throttle lever against stop inside of transmission.
7. With slight downward pressure on throttle control rod, adjust its length so that the clevis pin has a free fit. From the free-fit length, *shorten* the control rod by turning the clevis 3½ turns clockwise. Install clevis pin.
8. Adjust accelerator pedal height by turning threaded trunnion on accelerator connecting link until the pedal is 4¼″ from floor pan. Measure from top rear corner of pedal to floor pan.
9. If transmission operation is not satisfactory after the foregoing adjustment, the throttle control rod may be lengthened or shortened 2½ turns from the above 3½ turns. If operation is still unsatisfactory, conduct a pressure test as outlined in the *Two-Speed Fordomatic* chapter.

Manual Linkage Adjust

1. With engine stopped, loosen clamp at shift lever so that shift rod is free to slide in clamp.
2. Position selector lever so that pointer lines up in "D" position.
3. Shift manual lever at transmission into "D" detent position (second from rear).
4. Tighten clamp on shift rod and check pointer alignment in all positions.

Starter Neutral Switch Adjust

1. Check starter circuit in all selector lever positions. Circuit must be open in all positions except "N" and "P".
2. To adjust switch, loosen switch-to-steering column screws. Position switch so that starter circuit is closed when selector lever is at "N" and "P" only.

VACUUM CONTROLLED THROTTLE LINKAGE

Late 1961 & 1962

1. Referring to Fig. 4, apply parking brake and place selector lever at "N".
2. Warm up engine to operating temperature and adjust idle speed to 485 rpm.
3. With throttle in hot idle position, bottom dashpot plunger and measure clearance between plunger and throttle shaft lever. Dashpot clearance should be $\frac{5}{64}$″ on Falcon and $\frac{9}{64}$″ on Comet.
4. With engine stopped, adjust carburetor throttle rod length to obtain an accelerator pedal height of 4½″ on Falcon and 4 5/16″ on Comet—meas-

ured from top front corner of pedal to floor mat.
5. Disconnect throttle return spring and downshift linkage return spring.
6. Loosen adjustment screw on downshift control rod.
7. Pull control rod and throttle linkage Z-bar up to limit of their travel. Then, holding them in this position, slide adjustment screw down against the Z-bar, and tighten the screw.
8. Install return springs, and check throttle and downshift linkage for full travel.

Automatic Trans. Replace

1. Pull back floor mat and remove converter housing-to-engine bolt access hole covers. Remove two upper bolts which attach converter housing to engine.
2. From under hood, remove two bolts attaching throttle linkage bracket to converter housing.
3. Remove starter. Then raise car on hoist.
4. Remove converter housing bottom cover.
5. Drain converter and transmission.
6. Remove propeller shaft.
7. Disconnect linkage at transmission.
8. Disconnect oil filler tube.

Fig. 4 Vacuum controlled throttle linkage. Late 1961 and 1962

9. Remove engine rear support-to-extension housing bolt.
10. Disconnect parking brake cable rod at equalizer lever.
11. Place jack under transmission and raise it slightly to take weight off engine rear support member.
12. Unfasten support member from underbody (2 bolts) and remove support member.
13. Lower transmission and support engine.
14. Detach converter from flywheel (4 nuts) and remove converter away from flywheel as far as it will go.
15. Remove two lower converter housing-to-engine bolts.
16. Work converter housing off engine block dowel pins and work converter pilot out of engine crankshaft.
17. Secure converter to its housing and lower transmission.
18. Reverse above procedure to install.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

In this type axle, Fig. 1, the splined companion flange is fastened to the pinion shaft with a nut and flat washer which seats in the flange counterbore. The drive pinion is mounted on tapered roller bearings. Adjustment of the pinion along its axis is obtained by shims placed between the rear bearing inner race and pinion shaft shoulder. Adjustment of pinion bearings is obtained by tightening the companion flange nut which compresses a spacer over the pinion shaft between the two bearings.

Axle Shaft, Replace

1. Remove wheel and tire.
2. Back off rear brake shoe adjustments and remove brake drum.
3. Working through hole provided in axle shaft flange, remove nuts that secure wheel bearing retainer. Then pull axle shaft out of axle housing with a slide hammer type puller. *The brake carrier plate must not be dislodged; install one nut to hold plate in place after axle shaft is removed.*
4. If the rear bearing is to be replaced, loosen the inner retainer, Fig. 1. The retainer will become loose on the shaft if it is nicked deeply in several places with a chisel.

Drive shaft and universal joints

5. Remove bearing from shaft, using a press or puller. The new bearing should be pressed on the shaft so that it seats firmly against the shoulder on the shaft. Then press the retainer on the shaft until the retainer seats firmly gainst the bearing.
6. If the axle shaft oil seal is to be replaced, remove the seal with a slide hammer tool and install the new seal with a suitable driver.
7. Reverse the above procedure to install the axle shaft.

Rear Axle Repairs

The threaded nut type of differential

Fig. 1 Exploded view of rear axle assembly (4 pinion differential also used)

bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, is given in the *Rear Axles* chapter.

Drive Pinion Oil Seal Replace

1. Loosen but do not remove the carrier casting rear cover to drain the lubricant.
2. Referring to Fig. 1, disconnect drive shaft from drive pinion flange.
3. Mark pinion shaft nut, the end of pinion shaft, and pinion shaft splines for realignment.
4. Use a suitable tool to keep the flange from turning while removing the pinion shaft nut and flat washer.
5. Pull off flange and remove pinion oil seal.
6. Clean oil seal seat, and be sure that seal lubricant return passage is clear.
7. Coat outer edge of new seal with oil-resistant sealer and install seal.
8. Align flange spline mark and pinion shaft spline mark and install flange.
9. Install nut and flat washer and tighten nut until marks are aligned.
10. Complete installation of remaining parts and torque cover bolts to 20-25 ft. lbs.

Inspection Before Removing Axle

After removing the axle shafts as outlined previously, wipe the lubricant from the internal working parts and visually inspect the parts for wear or damage. Rotate the gears to see if there is any roughness which would indicate defective bearings or chipped gears. Check the gear teeth for scoring or signs of abnormal wear.

Check the differential case and drive pinion for end play. Set up a dial indicator and check backlash at several points around the drive gear. Backlash should be .005-.010″. If no obvious defect is noted, check the gear tooth contact as explained in the *Rear Axles* chapter.

Loosen the differential bearing cap bolts and torque them to 5 ft. lbs. Remove the adjusting nut locks and carefully loosen one of the adjusting nuts to determine if any differential bearing preload remains. If at least one notch of preload remains, the differential bearings may be re-used provided they are not pitted or damaged.

Drive Pinion Replace

To compensate for machining tolerances, pinion and ring gears are factory tested for tooth contact and quietness. This test is conducted at a standard cone setting, using an .018″ shim between the pinion rear bearing cone and pinion gear, and varied to obtain correct tooth contact and quietness. Shims of various thicknesses are used to obtain the desired result.

Note the figures etched on the rear end of the drive pinion. One set will be found identical on both the ring gear and pinion. This denotes a matched set of gears. Another figure will be found on the end of the drive pinion which shows a plus or minus sign. This indicates the position of the pinion in relation to the center line of the axle. If there are no figures showing a plus or minus sign, it denotes a zero pinion setting and an "O" will be shown.

The gear is marked + (plus) or — (minus) the number of thousandths of an inch that the gear varies above or below standard. Thus + means the pinion is closer to the center line of the axle than standard and the — mark means farther from the center line.

When installing a new ring gear and

pinion set or a new rear bearing, use new adjusting shims. Adjusting shims are available in thicknesses of .006, .007, .008, .012, .014, .016, .017 and .018 inch to obtain various thickness combinations.

The amount of shims used is determined by the amount of shims removed at disassembly and by the + or — figure etched on the pinion. For example, if the original pinion is marked +2 and had a shim pack of .015″ and the new pinion to be installed is marked —1, the shim pack must be increased by .003″ to bring the new pinion to the correct position. The new shim pack, therefore, will be .018″ thick.

Insert the drive pinion in position. At this time, install the original shim pack on the pinion shaft shoulder. For every shim added to pinion depth adjustment, subtract a like amount from the shim pack. If the pinion depth adjustment is less, add a like amount to the shim pack. This will approximate the pinion preload setting.

To adjust the preload, hold the pinion flange from turning and tighten the pinion shaft nut. As the nut is tightened, the shaft is pulled into the front bearing cone and into the flange until the cone and flange have bottomed on the collapsible spacer.

From this point a much greater torque must be applied to turn the nut since the spacer must be collapsed. From this point, also, the nut should be tightened very slowly and pinion shaft end play checked often so the pinion bearing preload does not exceed the specified limits (10-16 inch pounds on used bearings and 17-27 inch pounds on new bearings).

If the pinion nut is tightened to the point that bearing preload exceeds the limits, the pinion shaft must be removed and a new collapsible spacer installed. *Do not decrease the preload by loosening the nut as this will remove the compression between pinion front bearing cone and the collapsible spacer and may permit the front bearing cone to turn on the pinion shaft. As soon as there is preload on the bearings, turn the pinion shaft in both directions several times to seat the bearing rollers.*

MASTER CYLINDER REPLACE

1. Disconnect rubber boot from push rod end of master cylinder.
2. Disconnect brake lines from brake fitting and disconnect stop light switch wires.
3. Remove attaching bolts and remove cylinder from push rod and engine compartment.
4. Reverse above procedure to install and torque retaining bolts to 12-18 ft. lbs.

Front End and Steering Section

WHEEL ALIGNMENT

Caster and camber can be adjusted by removing or installing shims between the inner shaft of the front suspension upper arm and the underbody, Fig. 1. Both adjustments can be made at the same time by loosening the nuts on the two bolts that fasten the shaft to the underbody. After the adjustments are made, torque the nuts to 65-90 ft. lbs.

Adjusting shims are available in thicknesses of $\frac{1}{32}$″ and ⅛″. The $\frac{1}{32}$″ shims should be placed against the fender housing sheet metal or between the ⅛″ shims.

Caster Adjust

The removal of shims at the front bolt or the installation of shims at the rear bolt will decrease caster angle. The removal of shims at the rear bolt or the installation of shims at the front bolt will increase caster angle. A $\frac{1}{32}$″ change of shim thickness will change the caster angle approximately ½ degree. The difference between the shim pack thickness at the two bolts should not exceed $\frac{1}{16}$″.

Camber Adjust

The removal of equal shims at both bolts will decrease camber angle. The installation of equal shims at both bolts will increase camber angle. A $\frac{1}{16}$″ change of shim thickness at both bolts will change camber angle ⅓°. The total shim pack thickness at each bolt should not exceed $\frac{9}{16}$″.

Toe-In Adjust

Check the steering wheel spoke position when the front wheels are in the straight-ahead position. If the spokes are not in their normal position, they can be properly adjusted while toe-in is being adjusted, Figs. 2 and 3.

Fig. 1 Location of caster and camber adjusting shims

1. Loosen two clamp bolts on each tie rod sleeve.
2. Adjust toe-in.
3. When toe-in and steering wheel are correct, torque the clamp bolts to 11-14 ft. lbs. *Sleeve position should not be changed when clamp bolts are tightened.*

WHEEL BEARINGS ADJUST

After removing wheel cover and grease cap from hub, rotate wheel hub while torquing the adjusting nut to 11-14 ft. lbs. Then back off the nut at least ⅛ turn but not more than ¼ turn.

Loosen the adjusting nut just enough to line up the nearest slot in the nut with the cotter pin hole in the spindle, and install cotter pin.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that control arms are tight. Then check ball joints as follows:

The prescribed method of checking ball joints is by means of a dial indicator measurement of wheel movement at both upper and lower joint. With the car jacked up at the lower control arm or at the jacking pads, the indicator stem is placed on the wheel rim next to the lower ball joint position. As the wheel and tire are forced in and out, the indicator reading shows the amount of lower ball joint wear. Reading should not exceed ¼″.

To check for upper joint wear, the indicator stem is placed on the wheel rim next to the upper ball joint and the lateral pressure is exerted on the tire at this point. Again, if the reading exceeds ¼″, joint should be replaced.

FRONT END REPAIRS

Shock Absorber Replace

1. Raise front of car and place supports under both lower suspension arms.
2. Remove shock absorber retaining nuts from spring lower retaining plate.
3. Remove shock absorber upper bracket nuts and lift the bracket and shock absorber from car, Fig. 4.
4. Reverse above procedure to install.

Fig. 2 Steering tie rod sleeve adjustment

Fig. 3 Toe-in and steering wheel spoke adjustments

Upper Ball Joint Replace

1. Raise car high enough to provide working space and place a support under the upper arm, Fig. 5.
2. Remove wheel and tire.
3. Cut off rivet heads with chisel.
4. Remove nut from upper stud and remove ball joint.
5. Clean end of arm and remove burrs from hole edges. Check for cracks in metal at holes and replace arm if cracked.
6. Attach new ball joint to arm, using only specified bolts, nuts and washers.
   Do not rivet new ball joint to arm.
7. Install and torque stud nut to 35 ft. lbs.
8. Lubricate ball joint and, after installing removed parts, check wheel alignment.

Wheel Spindle Replace

1. Raise car and place support tool, Fig. 5, under arm.
2. Remove wheel, drum and brake backing plate.
3. Disconnect tie rod from spindle.
4. Remove ball joints.
5. Position new spindle and torque stud nuts to 35-65 ft. lbs. Install cotter pins.
6. After installing parts removed check wheel alignment.

Front Spring Replace

1. Raise car and remove wheel.
2. Remove shock absorber.
3. Install safety stand at front end of underbody.
4. Use a suitable tool, Fig. 6, to compress the spring 2 to 2½".
5. Remove spring lower retaining nuts and remove spring.
6. Reverse above procedure to install and check wheel alignment.

Upper Arm Replace

1. Raise car and place support, Fig. 5, under the arm.
2. Remove wheel assembly.
3. Remove upper ball joint and spring.

Fig. 4 Disassembled view of 1961-62 front suspension. Except for the threaded steel bushings for the upper control arm, the suspension is similar to 1960 which has rubber bushings.

Fig. 5 Upper arm support tool showing dimensions for making same and method of installation

Fig. 6 Showing tool used to compress front coil spring for removal

4. Unfasten and remove arm, noting number and position of shims at each nut.
5. Reverse above procedure to install and check wheel alignment.

Lower Arm Replace

1. Raise car and place support, Fig. 5, under upper arm.
2. Remove wheel assembly.
3. Remove lower ball joint, stabilizer bar and strut retaining bolts.
4. Unfasten and remove arm.
5. Reverse above procedure to install and check wheel alignment.

HORN SOUNDER & STEERING WHEEL

1960-62

1. Disconnect blue-yellow band horn wire under instrument panel to left of steering column.
2. Press down evenly on horn button or ring and turn counterclockwise until it lifts out from wheel.
3. Remove horn ring and spring.
4. Mark steering wheel position to steering column. Then remove wheel nut and wheel.
5. Remove turn indicator lever and mechanism retaining screws and lift mechanism to one side.
6. Remove screw retaining horn button contact and pull contact and wire from steering column.
7. To install, reverse above procedure.

Fig. 7 Steering gear assembly

STEERING GEAR

Adjustments

1. Disconnect pitman arm from steering rod.
2. Loosen steering gear housing attaching bolts at underbody side rail to relieve possible binding between steering column and worm shaft, Fig. 7.
3. Loosen steering column bracket screws at instrument panel.
4. Partially tighten steering column bracket screws.
5. Torque steering gear housing attaching bolts to 25-35 ft. lbs.
6. Loosen sector shaft adjusting screw lock nut and turn screw counterclockwise.
7. Measure worm bearing preload by attaching an inch-pound torque wrench to steering wheel nut or hook a spring scale to steering wheel rim. Read pull required to keep wheel moving for at least one complete turn. If torque or preload is not within the limits 3 to 6 inch lbs., adjust as follows:
8. Loosen steering shaft bearing adjuster lock nut and tighten or back off bearing adjuster, Fig. 7, to bring preload within specified limits.
9. Tighten steering shaft bearing adjuster lock nut and recheck preload.
10. Turn steering wheel slowly to each stop. *Turn gently against stops to avoid damage to ball return guides.* Then rotate $2\frac{5}{16}$ turns to center ball nut.
11. Turn sector adjusting screw clockwise until 8-13 inch lbs. is necessary to rotate worm past center. *No perceptible backlash is permissible at 30° on either side of center.*
12. Tighten sector adjusting screw lock nut and recheck backlash adjustment.
13. Tighten steering column bracket bolts and connect sector shaft arm to steering rod.

Steering Gear Replace

1. Raise front of car and place on safety stands.
2. Remove pitman arm from steering shaft.
3. Remove steering gear bolts from underbody and disconnect gearshift rods(s) at shift lever(s).
4. Pull rubber seal up on steering column, fold floor mat aside and move dash panel insulation out of the way.
5. Remove screws from steering column weather seal on dash panel.
6. Remove steering column cover plates and gasket.
7. Disconnect horn and turn signal wires under instrument panel. On Fordomatic cars disconnect neutral switch wires.
8. Remove steering wheel, upper bearing sleeve and spring and turn signal lever.
9. Remove steering column clamp and insulator.
10. Slide column tube off steering shaft, guiding shift lever(s) through rubber seal at dash panel.
11. Remove steering gear out the front through engine compartment.
12. Reverse above procedure to install.

Steering Gear Repairs

1. Rotate steering worm until nut is in center of travel, Fig. 7.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined previously.

Speedometer, Radio and Windshield Wiper

SPEEDOMETER, REPLACE

1960-62

1. Disconnect cable at speedometer.
2. Remove screws and lift instrument cluster bezel, lens and cluster mask plate from cluster housing.
3. Remove retaining screws and remove speedometer from cluster housing.
4. Reverse above procedure to install.

RADIO, REPLACE

Comet 1960-62

1. Disconnect ground cable from battery.
2. Remove control knobs from front of receiver, and two control shaft nuts and washers.
3. Disconnect antenna lead-in cable and speaker plug.
4. Disconnect dial lamp wire and power lead at fuse panel.
5. Remove radio bracket retaining nut at left-hand side and bracket retaining screw at right-hand side. Then carefully remove radio.
6. To install radio, reverse above procedure.

Falcon 1960-62

1. Pull control knobs off and remove nuts retaining radio to instrument panel.
2. Disconnect antenna lead at right side of radio.
3. Disconnect speaker leads.
4. Disconnect radio lead wire at fuse panel and pilot light wire.
5. Remove radio right and left support bracket-to-radio retaining bolts.
6. Remove radio from panel.
7. Reverse above procedure to install.

WINDSHIELD WIPER

To remove wiper motor, disconnect wiper hose at motor. If equipped with electric wiper motor, disconnect battery ground cable. Loosen control cable retaining screw at motor. Unfasten motor from mounting bracket and remove motor.

Power Train Section

POWER TRAIN, REPLACE

The preferred method of removal and installation described below utilizes a special Power Train Cradle (J-7894), Fig. 1, mounted on a transmission jack with the car on a hoist. Equipment limitations may require a modified approach to this operation but certain precautions must be observed.

1. The complete power train should be supported only at the engine pan rail. Under no circumstances should it be supported on the pan itself.
2. No jacking fixture or floor support should be used unless it is capable of supporting the weight of the power train (approximately 460 lbs.).
3. The center of gravity or balance point of the power train is located approximately .200″ behind the front face of the cylinder block.
4. No jack should be used that does not permit the power train to be lowered *gradually*. This is essential to avoid damage to components when close clearances are encountered during removal.

Power Train Removal

When working in the engine compartment, insert a pin or bolt through the holes provided in the lid support to prevent accidentally unlocking the support.

1. Disconnect ground cable from battery and ground straps to engine.
2. Disconnect wires from coil, generator, oil pressure and temperature sending units.
3. Disconnect accelerator return spring and accelerator rod from carburetor cross shaft.
4. Raise vehicle on hoist.
5. Remove engine and rear shield seal retainers, Fig. 2.
6. Remove rear wheels and brake drums.

7. Remove axle shaft universal joints from differential carrier and remove axle shafts.
8. Remove wires from starter solenoid and disconnect speedometer cable.
9. Disconnect carburetor cross shaft rod from accelerator control idler rear lever and push rod up into engine compartment. Remove rear idler control lever rod.
10. Disconnect shift rod coupling on standard transmission jobs. On Powerglide models, disconnect flexible control cable, T.V. and accelerator rod.
11. Disconnect main fuel line and heater fuel line at hose connections. Plug lines from fuel tank.
12. On standard transmission models, disconnect clutch fork return spring and unhook clutch control cable clevis. Disconnect clutch fork pull rod. Loosen ball stud at clutch control cable cross shaft and remove cross shaft.
13. Remove emergency brake tension spring.
14. Remove rear engine grille.
15. Remove engine skid plate bolt.
16. Position transmission jack under engine, using Power Train Cradle J-7894 if available.
17. Remove two nuts from front engine mount (at transmission) and nut from rear engine mount. *If front engine mounting bracket and shims are removed from transmission, the same amount of shims must be replaced. Rear wheel toe-in will be affected if shims are altered.*
18. Lower power train gradually and watch for possible interference at the rear mounting and left rear lower control arm.
19. Remove exhaust pipe and muffler.

Power Train Installation

Reverse the removal procedure to install the power train. Be sure all harness wires, fuel lines and levers are out of

the way prior to installation of the power train to prevent damage.

SEPARATION OF POWER TRAIN COMPONENTS

Remove 3-Speed Transaxle From Engine

1. With power train removed, support transaxle with chain hoist or other suitable lift and a sling.
2. Drain transmission and differential carrier.
3. Remove starting motor.
4. Remove two screws securing clutch pull rod dust seal; then remove pin attaching pull rod to clutch fork.
5. Remove bolts securing differential carrier to clutch housing. Pull transaxle away horizontally to prevent damaging clutch shaft, using care not to damage clutch fork. Remove clutch shaft.
6. To complete operation, remove clutch fork and clutch release bearing from differential carrier. The fork is attached to the carrier by a ball socket and spring retainer which is easily slipped off to allow the release bearing to be slipped off its shaft in the carrier.
7. Separate transmission from differential carrier.

Assemble 3-Speed Transaxle To Engine

1. Couple transmission to differential carrier, using new gasket. Be sure to engage splines of transmission mainshaft to internal splines of pinion in differential carrier. Install four bolts and torque them to 24-32 ft. lbs.
2. Install clutch release bearing and clutch fork on differential carrier. The bearing slips over the shaft and the fork has a spring retainer and socket which attaches to ball stud on carrier.
3. Install clutch shaft in transaxle; then check distance from end of clutch release bearing shaft to end of clutch shaft. If fully engaged, dimension should be $2\frac{9}{16}$" (plus or minus $\frac{1}{32}$").
4. Align both holes in differential carrier and clutch housing. Pilot clutch shaft splines into the clutch; then secure differential carrier to clutch housing with bolts.
5. Connect clutch push rod to clutch fork with pin; then position and secure clutch push rod dust seal to clutch housing with two screws.
6. Install starter and fill transmission and differential carrier with lubricant to the proper level.

Fig. 3 Dial indicator and support mounted on transmission

Fig. 4 Measuring mounting difference with dial indicator and support (J-8364)

Remove Powerglide Transaxle From Engine

1. Place a pan beneath transmission oil pan and loosen nut securing transmission filler tube to oil pan and allow transmission to drain.
2. Disconnect short length of hose connecting vacuum modulator tube to carburetor balance tube.
3. Remove engine front shield.
4. Remove starting motor.
5. Disconnect converter from engine flex plate by removing the three attaching bolts via the access hole at the 12 o'clock position in the converter housing. The converter may be rotated by prying against the starter gear teeth on the converter housing with a screwdriver.
6. Support transaxle with chain hoist or lift and sling.
7. Unfasten differential carrier from converter housing; then pull transaxle away from engine. Remove converter and turbine shaft.

Assemble Powerglide Transaxle To Engine

1. Align converter with flex plate; then pilot converter hub into crankshaft. Align bolt holes in differential carrier and converter housing; then secure transaxle to converter housing by installing top left bolt (11 o'clock position).
2. Install flex plate-to-converter bolt (at 1 o'clock position) to prevent accidental turning of converter or flex plate and loss of attaching bolt alignment.
3. Fasten remaining converter housing-to-differential carrier bolts.
4. Install starting motor.
5. Install two remaining converter-to-flex plate bolts via access hole in converter housing. The converter can then be rotated to make the attaching points accessible by turning the converter with a screwdriver against the starter gear teeth.
6. Install engine front shield.
7. If transmission filler tube was removed from engine front shield, reinsert it through the shield at this time; then connect the vacuum modulator to the carburetor balance tube with a short length of hose.
8. Insert and secure filler tube into transmission oil pan.
9. Refill transmission with fluid.

Separate Powerglide From Differential

1. With transaxle separated from engine, place transaxle on a flat surface.
2. Pull turbine shaft carefully through transmission and carrier, being careful not to damage turbine shaft bushings on pump shaft splines.
3. Remove transmission governor.
4. Unfasten transmission from carrier and pull transmission straight away from carrier to prevent pump shaft from damaging bushings in transmission and pinion shaft.
5. Remove governor gear and selective spacer from pinion shaft of differential carrier.

Selective Thrust Washer Determination

For proper operation it is necessary that sufficient end play of the Powerglide components be maintained by selection of thrust washers of various thicknesses. In the Corvair transmission, selective thrust washers are used at two locations:

1. At the front of the transmission between the front pump body and clutch drum.
2. At the rear of the transmission between the rear face of the planet carrier hub and the front face of the governor gear.

From the serviceman's standpoint, the

POWERGLIDE REAR THRUST SPACER USAGE CHART

Indicator Reading	Spacers to Be Used
*.011—.038	NONE
.039—.053	.016
.054—.068	.031
.069—.083	.046
.084—.098	.046+.016
.099—.113	.046+.031
.114—.128	.046+.046
.129—.145	.046+.046+.016
.146—.155	.046+.046+.031

*If initial indicator reading is below .011", replace .088" thrust washer at the clutch hub—front pump with an .076" or .050" thrust washer, then repeat entire rear thrust spacer selection procedure.

Spacer	Part No.
.016"	6256827
.031"	6256828
.046"	6255664

Fig. 5

use of the selective thrust washers at both the front and rear is a distinct advantage as final transmission end play adjustment can be made at either end of the transmission, whichever is most advantageous. *Also, there is no condition in which the selective washers would be gauged at both locations. Thus, if the repair requires axle and transmission separation, make the washer selection at the rear. Of course, if they are not to be separated, the rear thrust washer is inaccessible and the selection must be made at the front.*

Prior to reassembly of the transmission to the differential carrier after any repair which required separation of these units, the rear selective thrust washer must be determined. *Be sure low band is properly adjusted to prevent disengagement or cocking the apply linkage before tipping the transmission in its end.*

To determine the size spacer needed a dial indicator and a special support stand is available. Install the dial indicator on the support as shown in Fig. 3. Without gasket, place support J-8364 on rear pump cavity surface of transmission case so that dial indicator tip rests on planet carrier hub. Adjust indicator on J-8364 to permit maximum indicator travel and set dial at zero.

Slowly lift J-8364 and indicator off rear pump cavity and note its range of needle deflection from zero position. Properly positioned on support, indicator should not deflect more than .050" (one-half turn) when removed; otherwise raise or lower dial indicator on support post as required and again zero the gauge.

Place gauge and support on governor gear as shown in Fig. 4. Lower support slowly so that revolutions of indicator can be counted. Measurement starts once the indicator needle again reaches zero. Fully depress support on governor gear, note indicator reading and refer to Fig. 5 for spacers to be installed on governor gear. Install spacers selected at the front face of governor gear.

Assemble Powerglide to Differential

1. With new gasket in place, align carrier and transmission on a flat surface and guide pump shaft through differential carrier so as not to damage the bushing in the pinion. Then engage pinion shaft splines with planet carrier internal splines in transmission.
2. Install governor.
3. Secure transmission to carrier with four bolts. Drive the two bolts from the carrier side first and tighten to 24-32 ft. lbs.
4. Install turbine shaft, being sure to engage the two sets of shaft splines.
5. Install converter, being sure to get full engagement of splines on stator shaft, turbine shaft and front pump shaft. *Once the converter is installed, do not tip rear of transaxle downward unless some improvised converter holding plates are used to prevent converter falling off.*

Engine Section

On all service operations where threads enter aluminum, use an anti-sieze compound, such as Permatex No. 404 or its equivalent. Such service operations that can be performed with the engine in the vehicle will be so noted directly under the unit heading.

ENGINE DESCRIPTION

The engine, Fig. 6, is the horizontal opposed air cooled six-cylinder type. The cast aluminum alloy crankcase is vertically divided into two halves which are held together by bolts at the parting line. Each crankcase half has three pilot openings for individual cast iron cylinders which are positioned to the opening by means of four long studs at each cylinder. These studs pass freely through holes in the cylinder cooling fin structure and the cylinder head and serve to secure the cylinders and head to the crankcase.

The two opposing and identical aluminum cylinder heads incorporate cooling fins and built-in intake manifolds and contain wedge-shaped combustion chambers and valves for each cylinder. The valves are actuated by push rods through stamped rocker arms. Steel alloy valve seat inserts are provided for durability.

Steel tubes are used to house the push rods in the open area between the crankcase and cylinder heads adjacent to the cylinders. These tubes serve to protect the exposed push rods as well as drain back oil from the cylinder heads to a relatively shallow oil pan bolted to the bottom of the crankcase, Fig. 7.

The camshaft, which actuates the push rods through hydraulic lifters, is nested between the two halves of the crankcase below the crankshaft. This camshaft differs from the conventional design in that each of the three exhaust valve lobes are twice the width of the intake valve lobes and actuate a pair of exhaust valve lifters. The camshaft journals ride directly on the machined base metal of the crankcase. Camshaft end thrust is taken by a thrust washer located between the camshaft gear and front bearing.

No separate main bearing caps are required since the four bearings are supported entirely by the crankcase halves. The crankshaft drives the camshaft through a composition gear and drive hub. The front crankshaft seal is installed to the aluminum clutch housing (or flywheel housing) which mounts to the front of the crankcase assembly.

The engine rear housing mounts to the rear of the crankcase over four free-fitting long studs. This housing contains the oil pump, crankshaft seal and primary oil passages, Fig. 8. It provides the mounting for the distributor and the generator adapter to which the fuel pump, oil fill pipe, generator, oil filter and idler pulley are mounted.

A rectangular crankcase cover mounts to the top of the crankcase and forms a base for the centrifugal blower.

Cooling System

The engine is entirely shrouded with sheet metal pieces that attach directly to the engine and form a plenum chamber—a condition in which the pressure of the air in an enclosed space is greater than that of the outside atmosphere.

A centrifugal blower, mounted to the top of the crankcase cover, spins on a vertical shaft to deliver cooling air outward and downward over the cylinders and heads. The air then enters a duct under each bank from where it travels rearward to be exhausted at an opening at the rear of the engine.

The rate of engine cooling is regulated by a bellows-type thermostat at the lower part of the plenum. This thermostat operates a cooling air valve which moves in and out of the eye of the blower to control the air flow. The ring closes the blower air intake until the engine has reached its correct operating temperature. In the event of a failed thermostat bellows, the ring will remain in the open position to prevent overheating of the engine.

The blower, which runs on a sealed, permanently lubricated ball bearing, is belt-driven by a pulley mounted at the extreme rear end of the crankshaft. A generator drive pulley at the left rear of the engine and an idler pulley at the right rear provide a means of changing belt direction from a vertical plane at the crankshaft pulley to a horizontal plane at the blower pulley.

An oil cooler, through which a portion of the air passes before discharge, is mounted above the air exhaust duct near the left rear corner of the engine.

ENGINE DISASSEMBLY

Engine Out of Car

1. Remove transmission from power train.

2. Remove differential carrier from engine.
3. Remove clutch from engine (if equipped).
4. Remove carburetor linkage and related parts.
5. Remove blower belt.
6. Remove fuel pump.
7. Remove generator.
8. Remove engine front shield.
9. Remove vacuum balance tube.
10. Remove both carburetors.
11. Remove fuel lines and oil level gauge.
12. Remove distributor and spark plugs.
13. Remove coil and generator brace from cylinder head.
14. Remove engine upper shroud and side shields.
15. Remove oil filter and generator adapter.
16. Remove blower and pulley.
17. Remove crankcase vent tube.
18. Remove crankcase cover and blower bearing.
19. Remove engine front and lower shrouds and exhaust ducts.
20. Remove oil pan.
21. Remove exhaust manifold.
22. Remove choke heat tube at right cylinder head.
23. Remove engine rear mounting bracket and skid plate at engine rear housing.
24. Remove cylinder heads. *When crankshaft is turned for further disassembly cylinders will need a holding fixture which can readily be made. Six ½" x 4¼" long steel tubes to be used on long cylinder studs (one on each cylinder) and six ½" x 3½" long tubes for each short stud. Slip the tubes on the studs and keep them in place by means of the stud nuts, Fig. 9.*
25. Remove valve lifters with a magnet or wire hook.
26. Remove connecting rod caps, being sure they are marked so that they will be returned to the correct connecting rod.
27. Remove spring retainers and take off cylinder air baffle.
28. Remove each cylinder with piston and connecting rod as a unit.
29. Push piston out of cylinder with a hammer handle. *Ridges and/or deposits on upper end of cylinder can be removed after piston has been removed from cylinder with a cylinder mounted ridge reamer.*
30. Remove crankshaft pulley.
31. Remove engine rear housing.
32. Remove flywheel housing.
33. Remove snap ring and front oil slinger.
34. Loosen crankshaft bolts (8 long and 3 short bolts located on side of crankcase).
35. Place crankshaft on a block of wood at a 15° angle so crankshaft and camshaft will not fall out when crankcase half is removed.
36. Remove left crankcase half.
37. Remove camshaft by turning while lifting.
38. Remove crankshaft.
39. Press off camshaft and crankshaft gears.
40. Remove main bearing inserts.

Fig. 6 Engine cross section (top view)

Fig. 7 Cylinder head lubrication

ENGINE, REASSEMBLE

Crankshaft

1. To install crankshaft gear, mount shaft in an arbor press and support it between front crankshaft throw and front journal.
2. Press on crankshaft gear and install two woodruff keys.
3. Position fuel pump eccentric and spacer on shaft.
4. Lubricate crankshaft and distributor

TOP FACE OF ENGINE REAR HOUSING

BOTTOM FACE OF OIL FILTER AND GENERATOR ADAPTER

FRONT FACE OF ENGINE REAR HOUSING

REAR OF ENGINE CRANKCASE

Fig. 8 Engine lubrication

Fig. 9 Showing tubes holding opposite cylinder in place while torquing connecting rods

drive gear and install distributor drive gear.

5. Install oil slinger with concave side away from distributor drive gear.
6. Install crankshaft and main bearings.

Camshaft

Camshaft bearing journal clearance should be .0015″ to .0035″ new and .002″ to .004″ used. If clearance is not within limits either the crankcase or camshaft should be replaced.

1. To assemble camshaft gear and thrust washer to camshaft, firmly support shaft at back of front journal in an arbor press.
2. Place thrust washer over end of shaft and install woodruff key in keyway.
3. Lubricate camshaft with hypoid lubricant.
4. Install camshaft gear and press into place until it bottoms against thrust washer.

Timing Gear Marks

1. Install camshaft, guiding camshaft thrust washer into groove in crankcase, Fig. 10, while indexing camshaft gear to crankshaft gear so that valve timing marks line up as shown in Fig. 11.
2. Install other half of crankcase onto crankshaft and camshaft and fasten both halves together. Tighten bolts to the proper torque and in proper sequence.
3. Check camshaft end play, which should be .003″ to .007″.
4. Check timing gear backlash which should be .002″ to .004″.
5. Install front crankshaft oil slinger on crankshaft gear with flange side toward crankcase. Install slinger retaining snap ring, using care to avoid scratching sealing surface.
6. Install main oil gallery plugs with Permatex 404 anti-freeze compound or its equivalent.
7. Install flywheel housing with new gasket and torque bolts to 20-30 ft. lbs.

Fig. 10 Installing camshaft in crankcase

Pistons, Cylinders and Rods

1. Push piston into cylinder with hammer handle while holding cylinder in one hand until it is slightly below top of cylinder bore. *Notch on piston top must be installed towards front of engine (flywheel end) on both banks.*
2. With pistons and cylinders installed, install rod bearings.
3. Position crankcase pins by turning crankshaft with pulley so that crankshaft journal is in line with piston and rod to be installed.
4. Place a piece of plastic hose with at least a $\frac{5}{16}$″ diameter over each rod bolt to protect shaft journal.
5. Install a new copper cylinder gasket over cylinder pilot, Fig. 12.
6. Push piston with hammer handle while guiding cylinder bore pilot into crankcase. Remove plastic hose from rod bolts and install rod bearing and cap. Torque rod nuts to 20-26 ft. lbs.
7. Install cylinder holding tubes (used previously on disassembly) on cylinder studs to hold cylinder in place. Continue procedure until all cylinders and pistons are installed. Fig. 9.
8. Install cylinder air baffles with retaining springs, Fig. 12. *Air baffles are not interchangeable.*

Crankcase Cover and Blower Bearing

1. Install new gasket on crankcase.
2. Install crankcase vent and another crankcase gasket.
3. Install crankcase cover and blower bearing and torque bolts to 7-13 ft. lbs.
4. Install crankcase vent tube and gasket.

Oil Pump Screen and Tube

If the original or a new oil pump screen and tube assembly is to be installed in the original crankcase, the outside diameter of the end of the tube will have to be tinned with solder before installing in crankcase.

1. Install oil pump screen and pick-up tube into cylinder case with pick-up screen positioned parallel to oil pan rails. Secure tube with clamp.

Fig. 11 Timing marks aligned for correct valve timing

Fig 12 Installing cylinder and piston. Tubes "A" and "B" are holding cylinders in place

Fig. 13 Installing cylinder head gaskets

Fig. 14 Installing cylinder head

Fig. 15 Installing rocker arm studs

Fig. 16 Cylinder head tightening sequence

Fig. 17 Installing push rod drain tubes

Fig. 18 Push rod installation

2. Coat threads on engine temperature and oil pressure sending units with anti-seize compound (Permatex 404) or its equivalent. Torque oil pressure unit to 45-65 ft. lbs. and temperature unit 35-45 ft. lbs.

Cylinder Head

Be sure all cylinder head gaskets are in cylinder head combustion chambers as shown in Fig. 13. Remove all cylinder retaining tubes from cylinder bank to which cylinder head is to be installed.

1. Install cylinder head, Fig. 14.
2. Install six flat washers and nuts on long studs, adjacent to intake manifold.
3. Install six new "O" rings, lubricated with lubriplate, in counterbore of cylinder head (location for rocker arm studs) and coat rocker stud bore with anti-sieze compound.
4. Install rocker arm studs, Fig. 15, with threads coated with anti-sieze compound.
5. Tighten nuts and rocker studs in sequence shown in Fig. 16. Torque nuts and rocker studs to 27-33 ft. lbs.

Push Rod Oil Drain Tubes

1. Lightly oil hydraulic lifters and install in their proper bores.
2. Install push rod oil drain tubes through cylinder head, Fig. 17. Place "O" rings, one on each end of drain tube as shown. Oil "O" rings and push in place at lifter bore in crankcase and cylinder head.
3. Install push rods with side oil hole up into valve rocker socket, Fig. 18 (blue band end).
4. On early production engines, install push rod guides in place over rocker studs and push rods and tighten bolts. *On late production engines, push rod guides are installed under valve rocker studs.*
5. Install rocker arms, balls and nuts loosely in place. Adjust valve lash as outlined elsewhere in this section, after installing distributor.

Final Assembly

1. Install engine rear housing.
2. Install crankshaft pulley. After pulley bottoms in place, back off retaining bolt one turn and then torque it to 60-80 ft. lbs. *Do not drive pulley in place as this will damage crankshaft thrust bearing and crankcase.*
3. Install oil cooler.
4. Install exhaust manifolds.
5. Install oil filter and generator adapter.
6. Install sheet metal removed.
7. Install wires, fuel lines, etc.
8. Install spark plugs.
9. Install oil pan. Check parting line to see if flywheel housing gasket is far enough up for good sealing.
10. Install fuel pump and add engine oil.

CYLINDER HEAD REPLACE

Engine In Car

1962 Service Note

Cylinder head service procedures are the same as previous models except that the automatic choke control rod passes through the head to reach the thermostat and must be removed before the head can be removed.

Fig. 19 Checking installed height of valve springs

1960-62

Left Bank Head:

1. Drain crankcase oil.
2. Disconnect battery cables and ground connection to engine.
3. Disconnect radio ground strap.
4. Remove carburetor intake hose (connected to air cleaner and carburetor).
5. Remove carburetor accelerator return spring and disconnect accelerator rod from carburetor.
6. Disconnect left-side carburetor cross-shaft support (2 screws) from carburetor.
7. Disconnect fuel line at carburetor.
8. Remove carburetor.
9. Remove long stud from carburetor mounting.
10. Remove wires and spark plugs.
11. *Loosen* all engine side shield retaining screws. *Remove* screw from engine side shield under carburetor, attached to cylinder head. Remove engine side shield.
12. Remove oil cooler (this allows engine rear shroud freedom of movement during cylinder head removal).
13. Raise car on a hoist and attach a suitable lifting fixture to power train. *See requirements for lifting and supporting power train as outlined at the beginning of this section.*
14. Remove both engine side seal retainers and engine rear seal retainers.
15. Remove engine rear center shield and seal assembly.
16. Remove lower engine shroud.
17. Remove exhaust pipe-to-manifold nuts.
18. Open french locks on exhaust manifold and remove holding clamp nuts.
19. Remove exhaust manifold.
20. Remove engine rear mounting cotter pin, nut and washer from below body rear mounting bracket.
21. Remove rocker arm cover while holding a pan below to catch oil draining from cylinder head.
22. Remove rocker arms, push rods and push rod guides. *Present production*

engines require removal of valve rocker studs to remove push rod guides.

23. Remove rocker arm studs, washers and "O" rings from head. Also, remove push rod guides from late production engines.
24. Remove "O" rings from bottom of push rod drain tubes with a pair of hooked tweezers.

To remove No. 5 exhaust push rod drain tube, it is necessary to remove the right side exhaust manifold.

25. Remove retaining nuts and washers retaining head.
26. Carefully lower engine assembly approximately 3" to clear cylinder head carburetor flange.
27. Remove cylinder head from crankcase studs.
28. Reverse above procedure to install the head and tighten head nuts in the sequence shown in Fig. 16.

Right Bank Head: Removal and installation of the right bank head is essentially the same as the left head, except the coil, oil pressure and oil temperature sending units must be disconnected. Also remove the choke heat pipe and choke fresh air pipe from the exhaust manifold.

CYLINDER HEAD ASSEMBLE

Cylinder heads are identical except for location of vacuum balance tube hose connector which is on one side of the carburetor mounting pad on the right bank and the other side on the left bank.

1. Install each valve coated with SAE 30 engine oil in the valve guide from which it was removed or to the valve guide it was fitted.
2. Lightly coat valve spring shim with petrolatum to hold shim in place and place on valve spring seat.
3. Set valve spring in place on shim. Place valve cap in position, compress valve spring and install valve locks. *Each valve spring must have a hardened shim (.020" minimum) under it to protect aluminum surface. Service shims are available in .030" thickness.*
4. Check installed height of valve springs, Fig. 19. Reseating valves raises the installed height of valve springs and, if excessive, will have the effect of weak valve springs. If installed height of springs do not come within the limits illustrated, install a .030" shim. At no time should the spring be shimmed to give an installed height of less than the minimum limits.
5. Coat cylinder head and cylinder counterbore pilot with petrolatum to retain gasket and install new head gaskets, Fig. 13.

VALVES ADJUST

Engine In Car

1. After engine has reached normal operating temperature, remove the valve cover and install a reworked valve cover (cut the top out of a used valve cover) and gasket on cylinder heads to prevent oil from running out.
2. With engine running at idle, back off valve rocker arm nut until rocker arm starts to clatter.
3. Turn rocker arm nut down slowly until the clatter just stops. This is the zero lash position.
4. *Turn nut down ¼ turn and pause 10 seconds until engine runs smoothly. Repeat additional ¼ turns, pausing 10 seconds each time, until nut has been turned down one full turn from the zero lash position. This one turn preload adjustment must be done slowly to allow the lifter to adjust itself to prevent the possibility of interference between intake valve head and top piston.*
5. Adjust all valves in the same manner.

Fig. 20 Adjusting valves

ROCKER ARMS REPLACE

Engine In Car

1. Remove rocker cover and gasket.
2. Remove rocker arm nuts, balls and rocker arms.
3. Replace parts and adjust valve lash.
4. Install cover and gasket.

PUSH RODS REPLACE

Engine In Car

1. Remove valve cover and gasket.
2. Loosen valve rocker arms, balls and nuts from cylinder requiring push rod replacement.
3. Remove push rod and guide and install new push rod with .050" side oil hole up into cylinder head.
4. Adjust valve lash and replace cover and gasket.

VALVES, REMOVE

Head Removed

With cylinder head removed, use a suitable valve spring compressor to compress the spring in order to take out the valve locks. Then remove valve spring cap, spring, shim and valve. Repeat this operation on each valve assembly. Place valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to the original guide holes.

VALVE SPRINGS REPLACE

Engine In Car

1. Drain crankcase oil.
2. Remove valve cover and gasket.
3. Remove rocker arm nut, ball and rocker arm.
4. Remove spark plug from cylinder requiring valve spring replacement and use compressed air to hold valves in closed position.
5. Install a nut on rocker stud and use a forked tool as a lever to compress valve spring far enough to remove valve locks. Then remove spring cap and spring.
6. Install spring on spring seat shim with cap. Compress spring and install valve locks.
7. Install rocker arm, ball and nut and adjust valve lash.
8. Install valve cover and gasket.
9. Install engine oil.

Head Removed

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. Spring should be compressed to 1½" at which height it should check 58 to 64 lbs. Weak springs affect power and economy and should be replaced if not within 5 lbs. of the above limit.

If a testing fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that stands shorter than the new spring used for comparison should be scrapped. Of course, cocked springs should also be discarded.

VALVE GUIDES

Head Removed

Valve guides are an integral part of the head and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of three service valves with oversize stems (.003", .005" and .010").

After cleaning the valve guide holes, check the clearance with a dial indicator. Intake valve stem clearance should be .001" to .004" while exhaust stem clearance should be .002" to .005".

Clamp the dial indicator on one side of the rocker cover gasket rail, arranging the indicator so that movement of the valve stem from side to side (crosswise to head) will cause a direct movement of the indicator stem. The indicator must contact the side of the valve stem just above the cylinder head. With the valve head about $\frac{1}{16}$" off its seat, move the stem of the valve from side to side with light pressure to obtain a clearance. By trying new valves in the guide holes it can be determined whether the valves should be replaced or the bores reamed and oversize valves installed.

Service Note

A mid-year change in 1961 and carried

Fig. 21 Relation of valve and seat angles

over into 1962 replaces the tapered stem exhaust valves with straight stem valves and releases valve stems of .003″, .010″ and .020″ oversizes for service.

VALVES, GRIND

Head Removed

In refacing valves take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words the valve head margin must be at least $\frac{1}{32}$″ otherwise the valve must be replaced. The margin is the area above the contact surface of the valve face. The valve seat width after refacing should be $\frac{1}{32}$″ to $\frac{3}{32}$″ for intake valves and $\frac{1}{16}$″ to $\frac{1}{8}$″ for exhaust valves. Valve seat angle on all valves should be 45° and should be concentric within .002″ dial indicator reading. Valve face to seat angles are parallel as shown in Fig. 21.

VALVE SEAT INSERTS

Head Removed

When reconditioning valves, the exhaust valve seat inserts in the cylinder head should be inspected. If either valve seat inserts or valve guide bores are beyond repair, the cylinder head should be discarded and replaced with a new one.

VALVE LIFTERS REPLACE

Engine In Car

1. Drain crankcase oil.
2. Remove valve cover and gasket.
3. Remove engine lower shroud.
4. Remove rocker arms, balls, push rod guides, push rods and push rod drain tubes from cylinder from which valve lifter is to be removed.
5. Remove lifter with a strong magnet or:
   a. Remove snap ring retaining push rod seat and remove seat. Then remove lifter with a pair of pliers inserted in valve lifter snap ring groove.
   b. Remove oil pan and squirt lifter body with solvent to remove varnish from lifter body.
6. Install valve lifters well lubricated with engine oil.
7. Install push rod drain tubes with new "O" rings and set push rods in place on lifter seats with side oil hole up next to rocker arms.
8. Install push rod guides, rocker arms, balls and nuts, valve cover and gasket.
9. Install engine oil.

Lifters Out of Engine

1. Referring to Fig. 22, hold plunger down with a push rod and, using a small screwdriver or awl, remove push rod seat retainer.
2. Remove push rod seat and inertia valve, plunger and spring from lifter body.
3. Pull check ball retainer from plunger and remove ball and spring.
4. Clean all parts in solvent. If any parts are damaged, the entire lifter assembly should be replaced. The inertia valve in the push rod seat should move when the plunger is shaken.
5. Assemble lifter in reverse order of disassembly. Then compress plunger to open oil holes and fill plunger with SAE 10 oil. Work plunger up and down and refill.

EXHAUST MANIFOLD SLEEVES

1961-62

The exhaust sleeves are a press fit into the exhaust manifold.

1960

1. Remove exhaust manifold sleeves with a pipe wrench by turning gradually, Fig. 23. *Do not tap or pry sleeves from cylinder head.*
2. Check exhaust manifold sleeve installation holes in cylinder head for nicks or damage.
3. Coat new sleeves with anti-sieze compound and locate flat side parallel to exhaust push rod drain tube hole. Sleeves are installed with a press fit and must be started into place square with the exhaust bore in head. Sleeves are available in standard, .002″ and .010″ oversize for service.
4. Place sleeves in a container of dry ice for about 10 minutes.
5. Warm cylinder head to about 200° in boiling water or a suitable oven if one is available. *Do not use an open flame.*
6. Remove sleeves one at a time from the dry ice and tap into place.

Fig. 22 Hydraulic valve lifter

Fig. 23 Removing exhaust sleeves. 1960

PISTONS & CYLINDERS

Engine Disassembled

1. Using a block of wood for a fixture, drill two holes, spaced to provide a location for two long bolts. Holes should be small enough to require driving the bolts into the wood block. Clamp wood block in vise.
2. Install cylinder over bolts on wood fixture. Holding cylinder with one hand, Fig. 24, insert ridge reamer and remove ridge and/or carbon from cylinder.
3. Check cylinder walls for out-of-round or excessive ridge at top of ring travel. If cylinders are found to have taper or wear in excess of .005″, the cylinder and piston must be replaced.

PISTON RINGS REPLACE

Engine In Car

Bear in mind that cylinders and pistons are serviced as a unit and the operation outlined below is for replacing one or more pistons in one bank requiring ring replacement. It is not intended for complete piston and ring replacement.

1. Drain crankcase oil and remove cylinder head.
2. Remove cylinder from piston requiring new rings.
3. Remove old and install new rings. *Position oil control ring gap towards top of engine and compression rings with gap 45° from oil ring gap location. Rings must be installed with*

markings and inside bevel toward top of piston. Lubricate piston rings with engine oil and slide ring compressing tool, Fig. 25, over rings just enough to compress rings into piston.

4. Reverse above procedure to install parts removed. Add engine oil, start engine and check for oil leaks.

PISTON PINS

Engine Disassembled

Piston pins should be capable of supporting their own weight in either piston boss when coated with light engine oil at 70° temperature. Higher or lower temperatures will cause false indications. *Pistons, pins and cylinders are serviced as assemblies.*

ROD BEARINGS REPLACE

Engine In Car

1. Remove air cleaner element and carburetor intake hose.
2. Remove choke heat tube, choke fresh air hose and carburetor linkage.
3. Disconnect fuel lines at carburetor.
4. Remove left bank carburetor.
5. Disconnect choke link to choke assembly. Remove choke and air horn by removing nuts at legs of air horn support.
6. Disconnect spark plug wires.
7. Remove blower drive belt.
8. Disconnect fuel lines at fuel pump.
9. Remove carburetor cross shaft and vacuum balance tube.
10. Remove all engine upper shroud bolts and screws.
11. Remove screws on each side of front engine shield.
12. Disconnect cooling air throttle valve thermostat rod and remove cooling air throttle valve.
13. Remove all fuel lines.
14. Remove engine upper shroud, tipping front lip up so it clears front engine shield.
15. Remove blower pulley and blower.
16. Remove crankcase cover, gaskets and crankcase vent.

Fig. 24 Removing ridge and/or carbon from cylinder with ridge reamer

Fig. 25 Installing piston rings with aid of ring compressor (J-8356)

17. Remove spark plug from cylinder requiring new rod bearing and remove rod cap and bearing insert. Use a piece of $\frac{5}{16}$" plastic hose on each rod bolt to protect crankshaft journals from being scratched or marred.
18. Reverse above procedure to install parts removed. While tightening upper shroud bolts, rotate blower and check for interference at blower to upper shroud. Add engine oil, start engine and check for oil leaks.

Engine Disassembled

Rod bearing inserts are available in standard sizes and undersizes of .001", .002", .010" and .020". These bearings are not shimmed and when clearance becomes excessive the next undersize bearing insert should be used. *Do not file rod or caps in an attempt to fit bearings.*

Rod bearing clearance is checked with Plastigage in the same manner outlined for main bearings. If flattened Plastigage measurement is not over .003" (worn) or .002" (new) or not less than .001" the fit is satisfactory.

CRANKCASE

Engine Disassembled

1. Remove two oil gallery plugs located at flywheel housing end of crankcase. These passages should be cleaned with solvent.
2. Check cylinder pilot bores and bearing surfaces in each half of crankcase for nicks, cracks or other damage that would interfere with the proper fit of component parts.
3. Do not use scrapers or other sharp tools to clean gasket surfaces. A good cleaning solvent should be used to dissolve gasket material or varnish that may adhere to the surfaces.

Stud and Thread Repairs

Always use anti-seize compound (Permatex 404 or equivalent) on all threads entering aluminum.

To replace crankcase studs, install long and short studs as indicated in Fig. 26. Studs are available in oversizes of .003", .006" and .009".

It should require a torque of 10 to 30 ft. lbs. to install studs. If torque is less than 10, another selected stud should be used.

Heli-coils for thread repairs are available at local auto parts jobbers and should be installed to Heli-Coil prescribed methods.

All cylinder studs installed in crankcase adjacent to the main bearing webs have blind holes while the others do not.

MAIN BEARINGS

Engine Disassembled

Whenever the crankcase is parted, the bearings and crankshaft journals should be inspected. If upon inspection one half shows evidence of fatigue, distress, abrasion, erosion, scoring or the like, both crankcase halves should be replaced. *Never should one half be replaced without replacing the other half.*

If the running clearance of a bearing is too great with used bearing inserts, it will be necessary to replace both bearing halves. Should this become necessary, the crankshaft journal should be checked with a micrometer for out-of-round, taper or undersize dimensions.

Main Bearing Clearance

Main bearing clearance is checked with Plastigage, a wax-like material, available at auto parts jobbers.

To assure proper seating of the bearings, all crankcase bolts must be at their specified torque. Eight long $\frac{7}{16}$" bolts 42-48 ft. lbs., and three $\frac{5}{16}$" bolts 7-13 ft. lbs. Hold bolt head on $\frac{7}{16}$" bolts while tightening the nut. Do not tighten at bolt head. Fig. 27 shows tightening sequence. To check main bearing clearance, proceed as follows:

1. Starting with rear main bearing, remove one half of the crankcase while the other is supported on its side. Wipe oil from bearings and journal.
2. Place a strip of Plastigage the full width of the bearing (parallel to crankshaft on journal). *Crankcase*

Fig. 26 Installed length of crankcase and rear housing studs

Fig. 27 Crankcase tightening sequence

split line surfaces must be free of nicks and foreign matter.

3. Install other half of crankcase with bearings and evenly tighten crankcase bolts to proper torque. *Do not rotate crankshaft while Plastigage is between bearing and journal.*
4. Remove one half of crankcase. Then measure the width of the flattened Plastigage with the graduated scale on the edge of the Plastigage envelope.
5. If the flattened Plastigage is not over .004″ (worn) or .003″ (new) or less than .001″ the bearing insert is satisfactory. If not within these limits replace bearing insert.
6. A .002″ undersize bearing may produce the proper clearance. If not, it will be necessary to regrind the crankshaft journal for use with the next undersize bearing. Bearings are available in undersizes of .001″, .002″, .010″ and .020″.
7. Proceed to the next bearing. After all bearings have been checked and installed, rotate the crankshaft to see that there is no excessive drag.
8. Check the end play by forcing the crankshaft to the extreme forward position. End play should be .002″ to .006″.

OIL PAN REPLACE

Engine In Car

1. Drain crankcase oil and remove all bolts retaining oil pan to crankcase. Remove pan and discard gasket.
2. Install oil pan and torque retaining bolts to *40 to 60 inch lbs.*

OIL PUMP GEARS REPLACE

Engine In Car

1. Drain crankcase oil.
2. Place a piece of hardwood between oil pan rail and Power Train Cradle (J-7894). Install wood block adjacent to engine skid plate. Installation of wood block will allow easy removal of skid plate.
3. Disconnect engine rear mount and remove engine rear shield seal and center shield. Remove bolts from exhaust air ducts connected to the engine rear center shield plate.
4. Lower engine about 1″ to clear rear mount.
5. Remove rear mounting bracket and engine skid plate.
6. Remove oil pump cover and gears.
7. Reverse above procedure to replace parts removed. Torque mounting bracket nuts to 20-30 ft. lbs. and torque rear mounting nut to 40-60 ft. lbs.
8. After completing installation of remaining parts, add engine oil, start engine and check for leaks.

OIL PUMP REPAIRS

Engine Disassembled

1. When assembling the oil pump to the engine rear housing, install the idler gear on the shaft. Idler gear shaft should be .010″ to .020″ below gasket surface.
2. Place drive gear and shaft in pump housing.
3. Check projection of oil pump gears above gasket surface; this should be .0045″ maximum and .0025″ minimum. Clearance between gears and housing should be .005″.
4. Lubricate pump gears before installation. Install pump cover and tighten bolts.
5. Install a long screwdriver down the distributor mounting hole in the engine rear housing and turn oil pump drive shaft to see that pump turns freely.
6. Install pressure regulator valve, spring, gasket and plug.

OIL PUMP PRESSURE REGULATOR REPLACE

Engine In Car

1. Drain crankcase oil.
2. Remove right side exhaust air duct.
3. Remove pressure regulator plug, nylon gasket, spring and valve.
4. Install regulator parts, exhaust air duct and crankcase oil. *To check oil pressure, remove plug on top of oil filter and generator adapter, and install an oil pressure gauge. Start engine, check pressure, which should be 35 psi, and check for oil leaks.*

OIL COOLER & BY-PASS VALVES

Engine Disassembled

1. Referring to Fig. 28, remove oil filter by-pass valve by catching the inner edge of the valve with a suitable hook or small screwdriver.
2. Install the new filter valve with the spring *up* in the adapter housing.
3. Remove the oil cooler valve in the same manner as the filter valve. However, the valve spring should be installed *down.*

Fig. 28 Oil filter and oil cooler by-pass valve installation

OIL COOLER, CLEAN

Engine In Car

Remove the cooler access hole cover (under generator) and brush foreign particles away from oil cooler fins. Insert an air hose gun under the cooler and blow up through cooler fins.

OIL COOLER REPLACE

Engine In Car

1. Remove screws retaining oil cooler to engine shrouds, shields and cylinder head.
2. Remove cooler access hole cover (beneath generator) and remove long oil cooler mounting bolt and cooler.
3. Remove and discard worn seals from oil cooler adapter.
4. Invert cooler and allow oil to drain. Clean cooler fins with an air hose before and after cleaning in solvent.
5. Reverse above procedure to install.

Fig. 29 Installing oil pressure regulator stop groove pin

Fig. 30 Installing oil gallery plug

Tighten long retainer bolt 8-12 ft. lbs. Start engine and check for oil leaks around cooler and seal location.

OIL FILTER & GENERATOR ADAPTER

Engine In Car

1. To remove, release pulley belt tension at idler pulley and remove blower pulley belt. Disconnect battery ground and generator harness.
2. Remove generator and bracket.
3. Disconnect fuel lines at pump.
4. Remove bolts around oil filler tube; then remove all remaining bolts from adapter.
5. Remove adapter with fuel pump, oil filter and idler pulley as a unit.
6. Remove adapter gasket.
7. Reverse above procedure to install and torque adapter bolts to 7-13 ft. lbs.

CRANKCASE VENT TUBE REPLACE

Engine In Car

1. Remove engine upper shroud and blower pulley.
2. Remove retaining bolts and remove vent tube.
3. Install a new cork gasket over vent tube end, and insert in crankcase cover.
4. Install vent tube clamp and tighten bolt securely.
5. Install blower pulley and engine upper shroud assembly.

CRANKSHAFT PULLEY & ENGINE REAR HOUSING SEAL REPLACE

Engine In Car

On some engines the rear housing seal is installed with the flange on the inside, in which case the engine will have to be removed from the car and rear housing removed. If the flange is on the outside, proceed as follows:

1. Drain crankcase oil.
2. Disconnect battery cable to engine.
3. Remove all side shield seal retainers.
4. Remove engine rear center shield.
5. Remove engine skid bolt and attach Power Train Cradle (J-7894) to bottom of engine with car on a hoist.
6. Remove engine rear body grille and engine rear mount.
7. On standard transmission cars remove clutch return spring and disconnect clutch control cable and clutch pull rod.
8. Loosen outboard stud nut and slide it part way out of engine front mounting bracket slot.
9. Remove shift rod coupling.
10. Loosen front mounting nuts and lower engine until nuts are flush with end of studs (do not remove nuts).
11. Lower engine far enough to remove engine rear mounting bracket.
12. Remove oil filter and pulley belt.
13. Remove crankshaft pulley with a suitable puller. *Install bolts in pulley hub a depth of ¼" only, otherwise the bolts will damage the rear housing seal.*
14. Remove engine rear housing seal by prying on its outer edge with a couple of screwdrivers. *The lips of seal are packed with high melting cup grease for the life of the seal.*
15. Reverse above procedure to install parts removed. Add engine oil, start engine and check for oil leaks.

ENGINE REAR HOUSING

Engine Disassembled

When replacing the engine rear housing as a new unit, the following operations are required.

1. Install groove pin, Fig. 29, which holds oil pump pressure regulator valve in place.
2. Install oil pump gallery plug flush with counterbore, using sealing compound, Fig. 30.
3. Install new rear housing seal.
4. Install distributor holding stud 1⅛" measured from distributor pad on engine rear housing.

FLYWHEEL HOUSING SEAL

Engine Disassembled

1. Tap seal out of housing with a wood or fibre drift.
2. Clean flywheel housing seal surface with solvent and check surface for nicks or damage.
3. Lubricate outer seal surface (beaded area) with lubriplate or petrolatum and install with suitable driver. *If seal is removed and still usable, pack sealing lips with a good grade of cup grease with a high melting point (350°). New seals are packed with this type grease to last the life of the seal.*

Fig. 31 Blower bearing and crankcase cover

BLOWER BEARING, BLOWER & CRANKCASE COVER

Engine In Car

1. Disconnect battery ground cable.
2. Disconnect accelerator linkage and fuel lines.
3. Remove oil level gauge and fresh air choke at air cleaner. Remove choke pipe.
4. Remove air cleaner, air horn and support.
5. Remove carburetor vacuum balance tube and retaining strap at engine upper shroud.
6. Remove pulley belt and distributor wire harness.
7. Disconnect cooling air throttle valve lever swivel.
8. Remove engine upper shroud and thermostat rod as a unit. An alternate method is to remove the lower left shroud and remove clip from thermostat rod; then remove thermostat rod from engine upper shroud.
9. Remove blower pulley and blower (4 bolts) from blower bearing hub assembly.
10. Remove crankcase cover bolts and washers.
11. Remove crankcase - to - crankcase vent gasket and crankcase vent.

Blower Bearing Replace

1. While supporting crankcase cover, press blower bearing shaft out of blower.
2. Install new blower bearing hub assembly in crankcase cover, using hypoid lubricant on bearing shaft.
3. Press on shaft of blower bearing to a height shown in Fig. 31. *Do not press on bearing outer or inner race.*

Installation of Blower

1. Assemble crankcase cover, vent and gaskets as shown in Fig. 32.
2. Install blower and pulley bolts and torque to 20-25 ft. lbs.
3. Install engine upper shroud fuel lines and cooling air throttle valve

Fig. 32 Crankcase cover and vent. A. Vent. B. Cover. C. Gaskets.

assembly and tighten all retaining bolts. *When tightening upper shroud bolts, turn blower several times to make sure blower edge does not rub against upper shroud.*

4. Install remaining parts in the reverse order of removal.

BLOWER BEARING REPLACE

Crankcase Cover Removed

1. While supporting crankcase cover press blower shaft out of cover.
2. Install a new blower bearing hub in cover, using hypoid lubricant on bearing shaft.
3. Press on shaft of blower bearing and press assembly in place to a height of 4.520″ to 4.530″ parallel to cover gasket rails. Do not press on bearing inner or outer race.

COOLING SYSTEM THERMOSTAT

Engine In Car

In the event of a failed thermostat bellows, the cooling air throttle valve will remain in the open position allowing a maximum air flow over the engine to prevent overheating.

When installing a new thermostat it is necessary to adjust the cooling air throttle valve opening to provide the correct air flow. This adjustment must be made with the engine at normal operating temperature so the thermostat rod can easily be pulled up against the pull of the thermostat bellows. The adjustment is as follows:

1. With swivel inserted in hinge lever, pull up on thermostat rod until the bellows is stopped within its mounting bracket.
2. Measure the opening of the cooling air valve as shown in Fig. 33 and adjust the swivel to produce a 1½″ opening. This measurement is to be made below the center line of the air horn. *Do not pull up on the air throttle valve while making this adjustment—pull on thermostat rod only.*

Fig. 34 Ignition wiring

DISTRIBUTOR REPLACE

Engine In Car

To remove distributor, disconnect primary wire from coil. Remove distributor cap and vacuum line from distributor. Mark position of rotor arm on housing so that distributor may be reinstalled in same position. Unfasten and remove distributor from engine.

If necessary to remove secondary leads from distributor cap, mark position on cap tower for lead to No. 1 cylinder or see Fig. 34.

When installing distributor, turn rotor about ⅛ turn counterclockwise past the mark previously placed on distributor housing. Push distributor down into position in block with housing in normal installed position. It may be necessary to move the rotor slightly to start gear into mesh with camshaft gear but rotor should line up with mark when distributor is down in place. Fasten distributor in place and check ignition timing.

IGNITION TIMING

Connect a timing light to No. 1 spark plug and battery. Start engine and run it at slow idling speed. Aim timing light at timing mark. Adjust as required to bring the timing notch on the pulley in line with the dotted lines indicated for the timing marks present on the timing plate. Loosen distributor clamp bolt and rotate distributor body until timing is correct and tighten clamp bolt.

Fig. 33 Cooling air throttle valve adjustment

GENERATOR REPLACE

Engine In Car

Disconnect ground cable from battery, and wires from generator terminals. Remove drive belt, three attaching bolts and remove generator from engine.

Installation

1. Place generator in position and install bracket, leaving nuts loose.
2. Place blower belt over generator pulley but do not tighten idler bracket at this time.
3. Tighten two generator-to-engine oil filter attaching bolts and torque to 15-22 ft. lbs.
4. Snug up mounting bracket-to-generator bolt and nut (at commutator end) but do not tighten so that the bracket cannot move. Then finger tighten bracket-to-cylinder head bolts.
5. Tighten generator bracket-to-engine rear bolt to 15-22 ft. lbs.
6. Tighten mounting bracket-to-generator bolt (at commutator end) to 8-11 ft. lbs.
7. Tighten generator bracket-to-engine front bolt to 15-22 ft. lbs.
8. Adjust idler pulley so that there will be a ⅜″ deflection with a 15 lb. push midway between blower and idler pulley. Tighten idler pulley.
9. Connect generator wires to their proper terminals. On radio equipped cars, connect radio by-pass condenser to the armature (A) terminal —not to field (F) terminal.

STARTER REPLACE

Engine In Car

Disconnect wires and cable from starter. Unfasten and remove starter by pulling it forward to clear housing.

Reverse removal procedure and check starter operation.

Carburetor Section

CARBURETOR SYSTEM

1962

The 1962 engine uses two identical automatic choke, single barrel carburetors, Fig. 1, one located on each intake manifold. Each carburetor is separated from the manifold by an insulator block.

The automatic choke mechanism consists of a thermostat control coil mounted to the lower side of the cylinder head and linked directly to the carburetor choke valve shaft. A vacuum diaphragm, mounted on the carburetor air horn, replaces the conventional choke vacuum piston, to provide the start and run position of the choke valve. A fast idle cam is provided to control engine speed during warm-up.

1961

The carburetor system is the same as 1960 models except that a manually-operated choke is used in place of the automatic device used formerly.

1960

The Corvair engine makes use of two identical Rochester "H" single barrel carburetors, one located on each intake manifold, Fig. 2. Each carburetor is separated from the engine manifold by an insulator block. Neither carburetor is equipped with an automatic choke, since the choke is in the centrally located air horn-air cleaner assembly at the top of the engine, Fig. 3. From the air cleaner assembly two air tubes direct filtered air to the top of each carburetor.

The two carburetor throttle shaft levers are connected by a cross shaft which is actuated by the accelerator linkage. Careful adjustment is imperative to insure that the carburetors are properly synchronized.

The air horn assembly, while separated from the carburetors, is a definite part of the carburetion system. Outside air passes through the air horn, through the air cleaners and arrives as clean filtered air at each carburetor, Fig. 4.

The automatic choke, choke modifier and fast idle linkage are located on the air horn and are controlled by the same cross shaft which operates the carburetors. Many adjustments normally performed at the carburetor are done at the air horn assembly.

Fig. 1 Exterior views of 1962 carburetor

Fig. 2 Rochester 1960-61 carburetor

Fig. 3 Carburetion system. 1960

The automatic choke vacuum source is located at the mid-point of the balance tube which extends between the two engine manifolds. The choke outside air source is located on the air cleaner. Clean filtered air is passed from the air cleaner, through the tubing beside the engine manifold to be heated, and thence back to the automatic choke housing.

SYNCHRONIZE CARBS

1962

1. Perform the following adjustments on each carburetor (in sequence) with both throttle rods disconnected at the cross shaft, choke control rods disconnected at choke levers and with engine shut off.
2. Back idle speed screw away from throttle lever. Open choke valve so throttle lever does not ride fast idle cam. Place a .003″ feeler gauge between idle speed screw and throttle lever. Turn screw in until it just contacts gauge and then continue for 1½ turns more to set throttle valve.
3. Turn idle mixture screw lightly to its seat and back out 1½ turns.
4. Connect throttle rod to right-hand carburetor cross shaft lever, using clip.
5. To connect left carburetor, rotate cross shaft (with accelerator rod) to insure positive closing of right carburetor throttle valve. Adjust throttle rod length in swivel until rod freely enters hole on carburetor cross shaft lever. Then shorten rod one more turn in swivel. Secure rod with clip. *It may be necessary to hold choke valve open so fast idle cam is clear of throttle lever.*
6. The carburetors are now mechanically synchronized. Any further idle speed or mixture adjustment must be duplicated on both carburetors.

Fig. 4 Air routing to carburetor. 1960

1960-61

1. Detach and lift off air cleaner and air hoses as a unit.
2. Disconnect throttle rods from each carburetor.
3. Fully back off each idle speed screw on each carburetor so that each throttle valve is fully closed.
4. Place a .003″ feeler between idle speed screw and throttle lever. Turn screw down until it just holds gauge. Remove gauge and turn screw one complete turn more. Perform this operation on each carburetor.
5. Reconnect the throttle rod to the right carburetor and the throttle rod swivel to the left-hand cross shaft lever. Be sure the left-hand cross shaft lever is turned fully clockwise to insure that the right hand carburetor throttle valve is fully closed. Lifting up on the left-hand carburetor throttle rod, adjust the swivel at the top of the rod so that it freely enters the hole in the cross shaft lever.
6. The two carburetors are now synchronized. Any further curb idle speed screw adjustment must be duplicated on both carburetors.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

ROCHESTER CARBURETOR ADJUSTMENTS

ROCHESTER NOTES

①—Turn adjusting screw against high step of fast idle cam until the specified engine RPM is obtained.

Fig. ②—Float level. If float has no dimple, take measurement from center of float.

Fig. ③—Float level.

Fig. ④—Float drop.

Fig. ⑤—With throttle valves completely closed, bend pump rod as shown until index line on upper pump lever just aligns with sharp edge of air horn casting.

ROCHESTER NOTES

continued

⑥—With throttle valves wide open there should be the clearance listed between top of choke valve and adjacent wall of air horn. To adjust, bend unloader tang.

⑦—Adjust so that pointer lines up with index mark on choke housing cover.

⑧—With choke wide open, clearance between fast idle screw and pad (tang) on throttle lever should be .015" (.010" on 1960) on manual transmission and .030" on automatic transmission jobs. Adjust fast idle screw as required.

⑨—With engine stopped and throttle lever on second highest step of fast idle cam, bend tang to obtain the clearance listed between idle speed screw and throttle lever.

⑩—Hold vaccum diaphragm arm in against diaphragm. Clearance between lower edge of choke valve and wall of air horn should be as listed. If necessary to adjust bend diaphragm link. After this setting, throttle lever fast idle tang should rest on second highest step of fast idle cam. If not, adjust by bending outer choke shaft lever tang.

⑪—With choke control rod disconnected, hold choke valve closed. While holding control rod against stop in choke thermostat bracket, adjust upper choke control rod until it freely enters hole in choke shaft lever. Always turn vertical portion (not offset portion) of control rod. After engine warm-up, choke valve should be open and fast idle cam should clear throttle lever.

Clutch and 3-Speed Transmission Section

CLUTCH LINKAGE

1961-62

1. Disengage clutch pull rod from cross shaft.
2. Adjust length of front control cable at cross shaft clevis to obtain ½" to ¾" spacing between cross shaft pull rod lever and edge of transmission mounting bracket.
3. With pull rod held forward to remove slack at clutch fork, align rod swivel with upper hole in cross shaft lever; then back off swivel three complete turns and install pull rod assembly in upper hole of lever.

1960

The pedal should have at least ¾" travel before the clutch release bearing engages the clutch diaphragm spring. Check the clutch control cable and make sure that it is well anchored at the clutch pedal, Fig. 1, and engaged in each pulley.

1. Attach return spring, Fig. 2, to the cross shaft outboard lever lower hole. Clutch fork pull rod must be disconnected from cross shaft lever.
2. Adjust cable clevis, Fig. 2, until the outboard lever has a clearance of ⅛" to ⅜" as shown.
3. Manually pull clutch fork pull rod, Fig. 3, until slack is taken up at clutch fork.
4. With pull rod in this position, align swivel, Fig. 3, with upper hole in outboard lever. Back off swivel 3 complete turns and assemble to lever.
5. If service is required on the clutch linkage, refer to Figs. 1 and 4.

CLUTCH REPLACE

1. Remove engine, axle and transmission from the car and separate the axle and transmission from the engine as outlined in the *Power Train Section.*
2. The clutch fork, ball stud and clutch release bearing are removed with the axle housing.

Fig. 1 Clutch pedal components, 1960. Clutch pedal over-center spring not used in late 1961 and 1962

4. Return Spring

Fig. 3 Adjusting clutch fork pull rod. 1960

1. Cross shaft
2. Outboard lever
3. Clutch fork pull rod swivel
4. Clutch fork pull rod

3. Disconnect clutch fork from ball stud and remove clutch release bearing from shaft.
4. Remove 6 clutch attaching bolts, one turn at a time, until clutch spring pressure is released. Then remove clutch from engine.
5. Reverse above procedure to install the clutch, being sure the cushion springs of the clutch disc are located on the flywheel side of the driven plate hub.

THREE SPEED MANUAL TRANSMISSION

In essence the Corvair transmission is a conventional synchromesh type except for the use of concentric input and output shafts and its mounting on the differential carrier, Fig. 5.

Because of its mounting on the differential carrier, the mainshaft is hollow to permit the passage of the clutch shaft to the front of the transmission to the clutch gear. The clutch gear drives the counter gear and the remaining power flow sequence is identical to the conventional three speed transmission.

Shift Linkage Adjust

1962 Series 500, 700

1. Before making adjustment, lash in system is to be eliminated by moving shift control rod to rear.
2. With seat in full forward position, shift transmission to first gear, then loosen coupling nut on transmission shift control rod.
3. Adjust gearshift lever to ½ inch from edge of seat and tighten coupling clamp nut. Test shift in all ranges.

1962 Series 900

The adjustment procedure is similar to the 500 and 700 Series above except shift transmission into reverse gear and adjust shift lever a distance of 2¼ inches from the center of the shift lever housing (rearward) to the center of the shift lever knob.

After any service operation in which the shift control rod in the tunnel has been replaced or it has been found that transmission response is improper to the shift pattern, adjust the linkage as follows:

1. Loosen U-joint clamp nut and move transmission shift shaft so that the transmission is in Reverse. If position is doubted, start engine with clutch disengaged and then slowly release the clutch.
2. With an assistant holding the gearshift lever in Reverse, tighten the U-joint clamp nut.
3. Test shifts in all ranges.

Gearshift Lever Replace

1. Remove tunnel front plate.
2. Unfasten shift lever from floor pan (4 nuts). *The two rear nuts also secure the shift control shaft front mounting bracket.*
3. From driver's compartment, lift shift lever up until its studs clear the floor pan; then remove the unit by lifting the floor mat at the center of the seat.
4. If repairs are to be made, refer to Fig. 6.
5. Reverse above procedure to install lever assembly.

Shift Control Rod Replace

1. With tunnel cover removed, Fig. 7, fold back rubber boot covering control shaft U-joint at transmission end of shaft enough to expose connecting pin.
2. Remove connecting pin by pushing out with channel lock pliers.
3. Separate control shaft U-joint from transmission shift shaft by pushing control shaft out toward front of case.
4. Complete removal of shaft by removing two nuts attaching control

Fig. 5 Three speed transaxle (transmission and axle)

shaft front mounting bracket; then remove control shaft, U-joint and mounting bracket as an assembly.

5. Reverse above procedure to install.

Transmission Replace

Instructions for the removal of the power train from the vehicle and the separation of the transmission from the power train are provided in the *Power Train Section.*

Transmission Disassemble

1. Remove front cover plate and clutch gear bearing snap ring, Fig. 8.
2. Remove clutch gear and bearing (special puller J-8136).
3. Remove top cover.
4. Remove snap ring from mainshaft groove.
5. Drive or press mainshaft out of transmission.
6. Remove mainshaft parts by lifting out through top of case.
7. Expand snap ring and remove mainshaft rear bearing.
8. Drive countershaft out from hole in front of case, being sure to account for 25 needle rollers at each end.
9. Drive reverse idler shaft lock pin into the shaft; then drive the shaft out of the case through the hole at the rear of the case. The plug at the front of the case will be driven out by the shaft.
10. Remove detent cover and remove shift forks if necessary, Fig. 9.

Transmission Repairs

Reverse Idler Gear Bushings—Because of the high degree of accuracy to which these parts are machined, the bushings are not serviced separately. Check bushings for excessive wear by using a narrow feeler gauge between shaft and bushing. Proper clearance is from .002″ to .004.″

Countergear Needle Bearing—If wear is indicated on these bearings, they should all be replaced as well as the countershaft.

Clutch Gear Bearing—As the clutch gear bearing is removed as a unit, it will be necessary to drive the clutch gear out of the bearing if replacement of either the gear or bearing is required.

Fig. 6 Gearshift lever components.

3. Lever
4. Seat
5. Spring
6. Spherical joint
7. Retainer

Fig. 8 Manual shift three speed transmission components

Fig. 7 Tunnel shaft components

Fig. 9 Shift forks installed

Clutch Sleeve and Synchronizer Rings—

1. Remove first and reverse sliding gear.
2. Turn synchronizer ring in clutch sleeve until ends of ring retainer can be seen through slot in clutch sleeve.
3. Expand retainer into counterbore in clutch sleeve, Fig. 10. This raises retainer from groove in ring so ring may be slipped out.
4. Check synchronizer cones for wear or for being loose in clutch sleeve. If cones are damaged in any way, it will be necessary to replace the clutch sleeve and both synchronizer rings. Clutch sleeve should be replaced if there is more than .030″ end play between cone and snap ring.
5. Inspect synchronizer rings for smoothness.
6. Place the synchronizer rings in the cones and check with thumbs to see that rings do not rock. Excessive rocking indicates a poor fit between rings and cone, which will not permit proper synchronizing of gears during shifting.
7. Assemble synchronizer parts, being certain retainers seat in groove all the way around rings so rings will turn freely.

Synchronizer Energizing Springs—Under normal operation it should never be necessary to replace the energizing springs. However, should a spring be removed for any reason, a new spring should be installed. The spring may be removed by slipping a thin blade under the spring and raising it sufficiently to slide it off over the clutch gear teeth.

Install the new spring as shown in Fig. 11, thus keeping the spring from turning in its groove.

Transmission Assemble

1. Referring to Fig. 8, lubricate manual control shaft with oil and insert through seal in case. Position actuating finger and secure to shaft with two lock tabs and capscrews.
2. Install detent spring and ball, Fig. 12, in detent cavity. Tap to insure spring is resting on bottom of cavity.

Fig. 10 Removing synchronizing ring

Fig. 11 Position of energizing spring

3. Insert first and reverse shift fork through case, slip fork on shaft and secure fork to shaft with roll pin.
4. Insert interlock in detent cavity.
5. Insert second and third fork shaft through case and slip fork onto shaft. Twist shaft so its interlock groove is 90 degrees from the interlock; then fully insert shaft and twist shaft so interlock notch is engaged by interlock. Secure shift fork to shaft with roll pin.
6. Insert detent ball and spring for second and third shift fork, and install detent cavity cover and gasket.
7. Place some cup grease in roller bearing area of each end of countergear and install 25 rollers in each end. Grease will hold rollers in place while installing.
8. Apply grease to bearing thrust washers and countergear thrust washer and place one at each end of countergear. Tab on each washer should be positioned so as to align with notches in case.
9. Insert countergear in bottom of case.
10. Lubricate and insert countershaft in case.
11. Coat thrust washer and needle thrust bearing with grease and position them on reverse idler gear. Needle bearing against end (rear) with chamfered gear teeth. Coat bushings with transmission lubricant.
12. Place reverse idler gear in case with thrust bearing toward rear.
13. Install reverse idler shaft from rear, making sure lock pin hole in shaft lines up with hole in case at same angle.
14. Use new idler shaft lock pin and drive it in approximately $\frac{1}{16}''$ beyond flush with case.
15. Install mainshaft rear bearing in case until bearing contacts retainer ring in case. Then expand retainer and tap bearing until retainer ring seats in bearing groove.
16. Assemble mainshaft components, Fig. 13.
17. From the front, insert mainshaft through bores of second and third speed clutch and second speed gear; then install thrust washer on mainshaft with oil grooves toward gear.
18. Tap front of mainshaft until ring groove is accessible behind rear bearing and install snap ring. Check fit of snap ring by inserting feeler between snap ring and bearing inner race. End clearance must be .004″ maximum. Thrust washers are available in four thicknesses ranging from .086″ to .097″.
19. Place some cup grease in mainshaft pilot hole of clutch gear and install roller bearings and small spacer. Then install large spacer and remaining roller bearings.
20. Align synchronizer lands with clutch gear blank teeth.
21. Tap clutch gear bearing into case. Open retainer ring and fully seat bearing as indicated by seating of retainer ring in bearing groove.
22. Install front cover plate and gasket.
23. Install top cover and gasket.
24. Install expansion plugs in case openings at rear of manual shift shaft and reverse idler gear.

Fig. 12 Installing detent spring and ball for first and reverse shift fork shaft

Fig. 13 Mainshaft components

Powerglide Section

DESCRIPTION

The Corvair Powerglide transmission, Fig. 1, consists of an air-cooled, three element torque converter which drives through an automatic, two-speed planetary transmission.

As shown, the transmission is integrated to the differential carrier to form a Transaxle. As a result, the converter is remote from the main transmission, being separated by the differential carrier. Two shafts run axially through the hollow pinion shaft; one from the converter cover hub to the front pump and the other from the turbine to the input sun gear to transmit converter torque to the transmission gear box.

Excepting the converter location, mechanical components of the Corvair Powerglide are generally scaled-down versions of comparable parts in the conventional Powerglides used on Chevrolet cars. The use of a plate-type reverse clutch and a welded converter with integral starter driven gear are obvious exceptions.

MAINTENANCE & ADJUSTMENTS

Adding Oil

Oil level should be checked every 1000 miles. Oil should be added only when the level is near the "ADD" mark on the dipstick with oil at normal operating temperature. The oil level dipstick is located in the right front of the engine compartment. *The difference in oil level between "FULL" and "ADD" is one pint.*

To check oil level accurately, the engine should be idled with the transmission oil at normal operating temperature and the control lever in Neutral position. Oil level should be maintained no higher than the "FULL" mark on the dipstick. Do not overfill as foaming and aerating of the oil will result because the planetary unit will be running in oil, causing improper application of the band or clutches.

Draining and Refilling

No periodic draining of the transmission oil is recommended.

When the transmission requires repairs, drain the oil by loosening the filler tube attaching nut in the oil pan

Fig. 1 Corvair Powerglide

and allow the oil to drain (no drain plug is provided).

To refill the transmission, tighten the filler tube nut and add 4 pints of transmission fluid, using a suitable filler tube and funnel. Start engine and allow it to idle in Neutral for 3 to 5 minutes to warm the transmission fluid. Then add oil as required to bring the level to the "FULL" mark on the dipstick. Assuming that the converter was not drained (since it is welded) and allowing for nominal spillage or draindown, approximately 6 pints are required for a refill.

SHIFT LINKAGE

Check Operation

If improper shift linkage adjustment is suspected, a check can be made quickly without any disassembly as follows:

1. Start engine and allow to run for 2 to 3 minutes to warm up the transmission fluid.
2. With engine at normal idle speed, very slowly move range selector lever up from "N" to "R" and note by feel the point at which the reverse clutch applies. Properly adjusted, the reverse clutch should apply at the peak of the tooth separating Neutral and Reverse detents, Fig. 2.
3. Make the same check as in Step 2 while moving the selector lever from "N" toward "D". Properly adjusted, the low band should apply as the selector lever follower is felt to be at the tooth peak separating Neutral from Drive and full Drive detent.
4. Unless the shifts are obtained at the points illustrated, the shift linkage should be adjusted with Gauge J-8365, Fig. 3.

Adjustment

1. Drain oil and remove oil pan.
2. Place selector lever in "D".
3. Insert Gauge J-8365 into manual valve bore as shown in Fig. 3 with tab of gauge upward so it engages to forward port of valve body as shown in inset.
4. With gauge in place, push forward on manual valve levers. Properly adjusted, the gauge will be held in place horizontally without being supported.
5. If readjustment is required, loosen lock screw and push manual valve levers forward so that gauge is held in this attitude. Recheck adjustment as in Step 4.
6. When satisfactory adjustment is obtained, install oil pan and filler tube; then refill transmission with oil as described above.

Fig. 2 Shift linkage check diagram

Fig. 3 Adjusting manual valve linkage

Neutral Safety Switch Adjustment

Properly adjusted the neutral safety switch should prevent engine cranking when the ignition switch is turned to "Start" with the selector lever in any position other than "N."

To adjust, loosen switch mounting screws and place range selector lever in "N". Push switch in a direction towards front of vehicle as far as possible to extend plunger. Insert gauge (.680-.685") between end of plunger and switch; then move switch tightly against gauge and plunger and tighten two attaching screws while holding in this position. *A gauge 1"x$\frac{13}{32}$"x.680-.685" can be made from steel stock.*

Throttle Valve Linkage

As special linkage is not used to actuate the transmission throttle valve, refer to the carburetor portion of the *Engine Section* for adjustment procedure.

Low Band Adjustment

As no periodic adjustment of the low band is recommended, access to the adjusting screw has been provided from inside the vehicle via the parcel compartment area behind the rear seat.

To gain access to the low band, remove the parcel shelf and the plug covering the access hole in the floor pan.

Adjustment of the low band requires an improvised tubular hex ¾" socket approximately 4½ to 6" long. Probably the simplest way to fabricate this tool would be to weld two ¾" tubular stamped steel spark plug wrenches together.

To adjust, loosen the lock nut and tighten the adjusting screw *to 35 to 45 inch lbs., then back off 4 complete turns exactly.* While holding the adjusting screw stationary by means of the socket, inserted through the improvised wrench, tighten the lock nut securely.

"In Car" Repairs

CONTROL CABLE REPLACE

Remove tunnel covers and detach cable as suggested by Fig. 4. Install new cable as follows:

1. Lay cable out beneath car in its correct relationship.
2. Insert cable up into passenger compartment. Cable must then be routed *under* parking brake cable and then *over* parking brake pipe to prevent possibility of brake cable riding against shift cable.
3. Connect shift cable to range selector.
4. Shift range selector to "D" and secure cable to base of toe-pan.
5. Complete installation as shown in Fig. 4, being sure to bow cable to center line of vehicle to guide cable through hole in engine front support.

Fig. 4 Shift control cable routing

Fig. 5 Cable-to-case installation (early design)

Cable-to-Transmission Installation

Early Design, Fig. 5—With throttle rods disconnected from throttle valve lever on transmission, rotate throttle valve lever its full limit counterclockwise and insert cable ball into slot of transmission manual valve lever while guiding cable sheath stop into slot. Insert and tighten cable sheath nut 8-10 ft. lbs. *Torque is provided only as a guide but care must be exercised as overtightening can crack case at this area.*

Later Design, Fig. 6—Install O-ring seal on cable, having lubricated it with Lubriplate. With throttle rods disconnected from throttle valve lever on transmission, rotate throttle valve lever its full limit counterclockwise and insert cable ball into slot of manual valve lever. Fully seat O-ring and secure installation by installing capscrew and lockwasher.

Checking Installation, Fig. 7—Once fully tightened, exert a slight hand pressure in the counterclockwise direction and check that the hole in the notched arm of the throttle valve lever is *below* the

Fig. 6 Cable-to-case installation (later design)

transmission oil pan rail the dimension indicated by the arrows, Fig. 7 ($\frac{3}{8}$" plus or minus $\frac{1}{16}$"). If hole is above pan rail, cable installation is faulty and must be rechecked.

VACUUM MODULATOR

The vacuum modulator is mounted on the right side of the transmission and can be serviced from beneath the vehicle. Disconnect the vacuum hose and unscrew the modulator from the transmission with channel lock pliers or a thin one-inch wrench.

The vacuum modulator can be checked with a vacuum source for leakage. However, leakage normally results in transmission oil pull-over and results in oil smoky exhaust and continually low transmission oil level. No repairs are possible on the modulator; replace with new unit.

When installing, center the gasket in place with vaseline and hold it centered during installation to prevent an external oil leak.

GOVERNOR

Governor is accessible from beneath the vehicle and is mounted on the left side of the transmission. To remove, unscrew lock screw and pull the unit out of the transmission.

The only part replaceable is the driven gear. Drive out the roll pin with a punch and pull out the gear. Drill a new hole in the governor 90 degrees from the original; then insert a new gear and roll pin.

Fig. 7 Cable installation check diagram

Fig. 7A Remove valve body

When installing, use a new O-ring seal on the governor. Then insert the governor in the transmission with a slight twist to engage the gear teeth.

VALVE BODY & LOW SERVO

Removal

1. Drain oil pan and disconnect throttle valve rods from TV lever on transmission.
2. Remove oil pan and oil pick-up pipe.
3. Make an improvised sheet metal strap, Fig. 7A, and loosely install with one pan bolt.
4. Remove bolts securing valve body to transmission, tap valve body lightly with a soft hammer to loosen from its dowels in transmission case, then carefully lower the valve body about $\frac{1}{16}$", rotate improvised strap into place so it spans the servo piston hub and secure strap with pan bolt. This eliminates possibility of servo piston slipping down out of its bore and the loss of low band engagement with its apply components.
5. To remove the low servo piston, pull downward on the hub of the piston shaft with a screwdriver. *Do not remove piston in vehicle unless low band screw is first tightened fully.*

Valve Body Repairs

Referring to Fig. 7B, disassemble valve body as follows:

1. If installed, remove manual valve.
2. Remove screws and separate modulator valve body from main valve body. *Modulator body should be held during removal of screws as it is under spring pressure from the pressure regulator valve spring.*
3. Remove pressure regulator valve spring retainer, spring, and pressure regulator valve.
4. From the modulator body, remove rear pump priming ball and the front and rear pump check valves and springs. Also remove modulator valve.
5. To remove line pressure limiting valve, drive roll pin from modulator valve body with a punch, then remove line pressure limiting valve

spring and valve from their bore in the modulator body.

6. Remove screws and separate the transfer plate and gasket from the main valve body.
7. To remove the low drive shift valve components, remove retainer ring, then release the pressure and remove low drive regulator valve sleeve, regulator valve, spring seat and inner and outer springs. Lightly tap main valve body with a plastic mallet to remove the low drive shift valve from its bore.
8. To remove the TV valve components, remove retaining pin by wedging a thin screwdriver between its head and the surface of the main valve body, then remove detent valve assembly and throttle valve spring. Complete disassambly of the throttle body by removing the "E" ring from the throttle valve, then remove throttle valve from main valve body by tapping valve body with a plastic hammer.

Inspection

A thorough cleaning of all parts in clean solvent is mandatory. Check all valves and their operating bores for burrs or other deformities which could result in valve hang-up.

Assemble

Referring to Fig. 7B, complete assembly by reversing the foregoing instructions. Tighten screws to 38-50 *inch lbs.* and check shift cable adjustment as described earlier.

Low Servo Piston Repairs

Disassemble the servo piston by removing the hairpin clip. Remove ring from piston and install it in low servo bore to measure the ring gap which should be .002″ to .012″.

Assemble ring to piston and measure clearance between ring and one wall of piston groove which should be .0005″ to .005″.

Installation

1. Install low servo piston and return spring in transmission bore and engage notch in piston shaft with low band apply strut, loosening low band screw slightly to permit piston ring to seat in case bore.
2. Install valve body in transmission while simultaneously loosening low band screw until it is possible to index valve body on dowels in case. If manual valve is installed, index it with a manual valve lever in case; then secure valve body with 20 bolts to a torque of 9-11 ft. lbs.
3. Install O-ring in valve body and install oil pick-up pipe and secure with screw.
4. Complete installation and adjust low band as outlined previously.

Fig. 7B Valve body exploded

Service Operations, Power Train Removed

All operations which follow must be performed with the power train removed from the vehicle and mounted on the fixture used for its removal.

TRANSMISSION DISASSEMBLE

1. Drain oil and remove 12 bolts securing front pump to case.
2. *If overhaul is being made with the transmission installed on power train, loosen low band adjusting screw jam nut and fully tighten the adjusting screw. This will prevent the case components from being pulled out when front pump is removed, Fig. 8.*
3. Remove front pump cover and pull out pump shaft, Fig. 9. Remove front pump body from case, using care not to drop pump gears. Remove pump gasket.
4. Loosen low band adjusting screw and remove low band and related parts, Fig. 10.
5. Remove clutch drum, Fig. 11. *If operations are being performed with the transmission attached to the power train, care should be taken not to disengage the ring gear from the reverse clutch face plates unless replacement of either the ring gear or reverse plates is anticipated. Engagement of the reverse plates and ring gear in the horizontal position is generally difficult and should not be attempted unnecessarily.*
6. Remove planet carrier from ring gear and remove turbine shaft. On disassemblies made with the transmission separated from the axle, the turbine shaft is removed with the separation of the two units.

NOTE—The foregoing concludes the extent of disassembly which should be attempted with the transmission assembled to the power train. Although the reverse clutch plates are accessible without further tear-down, any failure of these plates can reasonably be assumed to be caused by malfunction of the reverse clutch, access to which requires the removal of the transmission from the power train. The remaining disassembly operations can only be performed with the transmission separated from the power train.

7. Remove ring gear, Fig. 12.
8. Remove clip, Fig. 13, mounted on the thick reverse reaction plate between the ends of the reverse clutch snap ring. Then remove snap ring.
9. Remove the thick reverse reaction plate, the three faced plates and the thin steel plates.

Fig. 8 Removing front pump with slide hammers

Fig. 9 Removing front pump drive shaft

Fig. 10 Low band components

Fig. 11 Removing clutch drum

10. Remove rear pump and reverse piston mounting bolts, which are accessible from the rear (differential carrier side) of transmission case.
11. Remove rear pump and reverse piston by pulling forward with a twisting action.
12. Remove rear pump wear plate from rear of case.

INSPECTION & REPAIRS

1. Referring to Fig. 14, wash all parts with solvent and dry with compressed air. Handle transmission case carefully to avoid damaging finished surfaces as such damage could result in oil leakage.
2. Inspect all mating surfaces of the transmission case for nicks and other damage and repair as required. Be especially careful to check the area around the manual shift cable as over-tightening the cable nut could possibly crack the case at this point. Check case bores for wear and grooves.
3. Inspect condition of ring gear teeth and splines.
4. Inspect governor drive gear, splines and teeth for wear.
5. Inspect rear pump wear plate for wear and abrasion.
6. If clutch drive plate facings are worn or show signs of intensive heat, replace plates. Reaction (steel) plates, unless external tangs are peened or damaged, are generally serviceable even after failure of drive plates.
7. In the valve body area of the transmission case, check that the priming ball is retained by its wire retainer and see that the ball and its seat in the case is not deformed. Repair any seat deformation and if ball is damaged, replace it.
8. Check manual valve and TV valve linkage. If damaged replace as required.
9. If necessary, remove valve body oil pick-up tube and clean screen. Also check that the O-ring seal used between the pick-up and valve body is in good condition.
10. Inspect condition of low band. If it shows signs of excessive heat, brittleness of facing can be expected and the band should be replaced.
11. Individual inspection and repair procedures are covered in the following text. The seven bushings used in the transmission are indicated in Fig. 15 together with the applicable bushing installer.

Fig. 12 Removing ring gear

Front Pump

1. Wash all parts and blow out oil passages.
2. If inspection shows that pump gears are serviceable, install gears and check:
   a. Clearance between OD of driven gear and body should be .0025-.005″.
   b. Clearance between driven gear and crescent should be .003-.009″.
   c. With scale and feeler gauge check gear end clearance, which should be .0005-.0015″.
   d. Inspect pump drive gear teeth for interference between tops of teeth and crescent in pump.
6. Replace gasket and square cut seal ring in OD of front pump cover. Also check condition of cast iron seal rings on pump body hub.
7. Check condition of front pump body bushing and replace if necessary.

Clutch Drum

1. Referring to Fig. 16, disassemble clutch drum as picture suggests.
2. Inspect clutch drum band surface for excessive scoring or burning. Also

Fig. 13 Reverse clutch pack retainer ring and clip

Fig. 14 Corvair Powerglide transmission

check drum bushing for scoring or excessive wear.

3. Check steel ball in clutch drum that acts as a relief valve. Be sure that it is free to move in the hole and that the orifice leading to the front of the drum is open. If the ball is loose enough to rattle, replace clutch drum as an assembly. Replacement or staking the ball should not be attempted.
4. Check fit of clutch flange in drum slots. There should be no appreciable radial play between these two parts. Also check low sun gear for nicks or burrs and bushing for wear.
5. Check clutch plates for burning, pitting or metal pick-up. Also check to see that the faced plates are a free fit over clutch hub and that the steel plates are a free fit in clutch flange. Check for excessive wear on friction facing of drive plate teeth. Check condition of clutch hub splines and mating splines on faced plates.
6. Assemble clutch drum in reverse order of disassembly, referring to Figs. 16 and 17.

Planet Carrier

Currently, no service operations are recommended for the planet carrier. If a component fails, replace the planet carrier as an assembly.

Turbine Shaft

Check the shaft for nicks and cracks and check the splined areas for wear. Check that the two lube holes are open. Also inspect the bushings and replace if necessary.

Pump Shaft

Check the splines at the converter end of the shaft for wear or damage. Inspect the bronze faced drive lugs for peened edges and wear of its splined connection to the shaft by twisting to check for looseness. Be especially careful to check that the drive hub is tightly retained by the snap ring. If bronze hub is worn, remove top snap ring and replace hub.

Rear Pump and Reverse Piston

1. Referring to Fig. 18, disassemble as picture suggests. The tools shown in Fig. 19, together with a press aids in disassembly.
2. Check fit of pump gears as described for the front pump. Fits and tolerances are identical.
3. Inspect pump body for leaks and scoring. Check hub of pump body for smoothness. Any burrs on the surface would cause leakage and could result in a jammed reverse piston.
4. Check for broken return springs and make a comparative check of spring heights by standing all springs in a row. If appreciable variance of spring height is noted, replace springs.
5. Check condition of rear pump body bushing and replace if necessary.

Converter

It is not necessary to drain the converter as it is welded and no internal repairs can be made.

Check the starter gear for worn or broken teeth and for broken welds at its attachment to the converter assembly. If starter gear is undamaged but welds are loose or broken, reweld as required.

Check converter seams for stress or breaks and either replace converter or repair welds as required. If welds are repaired, keep added material to a minimum by carefully chipping off all scale and filing away any unnecessary weld to obtain converter balance as close to original as possible. Replace the converter if roughness due to unbalance is noted after reassembly to engine. Check converter bushing for wear and replace if necessary.

Fig. 16 Clutch drum and component parts

TRANSMISSION ASSEMBLE

The following steps apply only if the transmission is separated from the Power Train.

1. Install two improvised guide pins in rear pump bolt holes. Install rear pump wear plate on guide pins, using a small amount of vaseline to hold plate in place.
2. Insert rear pump and reverse piston. Then insert a length (½" to ¾" wide) of .010-.015" shim stock between piston outer seal and case. With rear of case downward, running the shim stock around the entire diameter of the seal will seat the seal quickly. Remove guide pins and install rear pump mounting bolts, torquing them to 9-11 ft. lbs.
3. Install reverse clutch drive and reaction plates alternately starting with a steel plate, and finishing with a faced plate. The notched lug in each steel plate is installed so it is at the top of the groove at the 4 o'clock position in the case. Then install the thick reaction plate; it has a square "dimple" on its lug which engages the 4 o'clock case groove.
4. Install reverse clutch retainer ring in such a manner so that the open ends of the ring are at the 12 o'clock position; then install retainer clip (Fig. 13) on thick reaction plate between ends of snap ring.
5. With rear of transmission case downward, align internal lands and grooves of reverse face plates.
6. Engage ring gear to reverse drive plates, Fig. 12. Engagement must be made by feel while jiggling the drive plates laterally.
7. *On assemblies being performed with the transmission installed on the Power Train, install the turbine shaft at this point. Be sure to fully engage splines of turbine shaft to those in converter turbine.*
8. Install planetary unit with a slight twist to engage planet gears with ring gear. Be sure to engage the two rear pump drive lugs on planet hub with grooves in rear pump drive gear.
9. Install thrust washer on captive input sun gear in planetary gear set

Fig. 15 Powerglide bushings and installers

Fig. 17 Installing clutch drum plates

Fig. 18 Rear pump and reverse piston

with flange of thrust washer toward front of transmission. If necessary, apply a small amount of vaseline to keep thrust washer centered, especially if the work is being performed with the transmission assembled to the Power Train.

10. Install clutch drum assembly, using a slight twist to engage low sun gear to planet gears in gear set.
11. If assembly is being performed with transmission removed from Power Train, turn transmission to a horizontal position. Then install low band and its component parts, Fig. 20. *When the linkage is all installed, snugly tighten the low band adjusting screw to prevent struts from falling out of place.* Then jiggle clutch drum slightly to center band and linkage.

Front Selective Thrust Washer Determination

At this point, prior to the installation of the front pump when overhauling the transmission while assembled to the Power Train, the thrust washer selection must be determined with the tool shown in Fig. 21 as described below. *The use of this tool and the following procedure is absolutely limited to overhauls performed while the transmission is assembled to the differential carrier. At this point, during overhauls with the transmission separated from the differential carrier, install the original (unless necessary to replace) thrust washer on the front pump hub without gauging, and complete transmission assembly. Final end play adjustment would then be made at the rear (governor gear) as described in the Power Train Section.*

Insert pilot of tool into bore of clutch drum and secure with two front pump mounting bolts. Tighten bolts fully to compress pilot spring. See that the plunger is fully seated. Then observe plunger action and select thrust washer as instructed in Fig. 21. Remove tool and install thrust washer selected on front pump hub.

Fig. 19 Removing reverse piston return spring retainer

Final Assembly

1. Install front pump body with new gasket, being careful not to break cast iron oil ring on pump hub when they are indexed to clutch drum.
2. Install front pump drive shaft, Fig. 9. Use care when inserting shaft not to damage bushings in transmission.
3. Install a new square cut seal ring in front pump cover; then position pump cover. Dip bolt heads in oil impervious sealer and install bolts loosely. Tighten outer bolts in a criss-cross pattern to 18-20 ft. lbs. Then tighten five inner bolts to the same torque. By using this sequence, the chance of cocking the pump which would bind the pump hub to the pump shaft is avoided.
4. Adjust the low band by first tightening the adjusting screw until it bottoms; then back off four full turns exactly. Holding adjusting screw and tighten lock nut.

TROUBLE SHOOTING

The use of pressure checks for diagnosis of Corvair Powerglide malfunctions is not recommended at this time; therefore pressure test data are not provided.

No Drive In Any Selector Position; Cannot Load Engine

1. Low oil level.
2. Clogged oil pipe screen.
3. Broken or disconnected manual valve cable.
4. Front pump defective.
5. Front pump shaft disengaged at either converter or pump gear.
6. Front pump priming ball not seating.

Fig. 20 Installing low band components

7. Defective pressure regulator valve.
8. Defective line pressure limit valve.
9. Rear pump check valve and rear pump priming ball not seating. Both must occur for possible malfunction.

Engine Speed Flares On Standstill Starts But Acceleration Lags

Low band partially applied due to any of the following:

1. Low oil level.
2. Clogged pick-up pipe screen.
3. Improper band adjustment.
4. Servo piston apply passage blocked.
5. Servo piston ring broken or leaking.
6. Band facing worn.
7. Low band apply linkage disengaged or broken.
8. Converter stator not holding (rare).

Engine Speed Flares On Upshift

1. Low oil level.
2. Clogged oil screen or pipe.
3. High clutch partially applied (blocked feed orifice).
4. Clutch plates worn.
5. Clutch seals leak.
6. Clutch piston hung up.
7. Clutch drum relief ball not seating.
8. Vacuum modulator hose collapsed.

Transmission Will Not Upshift

Low band not releasing, probably due to:

1. Stuck low-drive valve.
2. Defective governor.
3. No rear pump output such as stuck

Fig. 21 Gauging clutch drum thrust washer with J-8371

priming ball, drive pins not engaged, or defective pump.
4. TV valve stuck or maladjusted.
5. Maladjusted manual valve lever.

Upshifts Harsh

1. Incorrect carburetor-to-transmission TV rod adjustment.
2. Improper low band adjustment.
3. Vacuum modulator hose broken or disconnected.
4. Vacuum modulator diaphragm leaks.
5. Vacuum modulator valve stuck.
6. Hydraulic modulator valve stuck.

Closed Throttle (Coast) Downshifts Harsh

1. Improper low band adjustment.
2. Vacuum modulator hose disconnected or broken.
3. Vacuum modulator diaphragm ruptured.
4. Vacuum modulator valve stuck.
5. Engine idle speed too high.
6. Sticking valves in valve body (pressure regulator or hydraulic modulator valves).

Car Creeps In Neutral

1. Incorrect manual valve lever adjustment.
2. High clutch or low band not released.

No Drive In Reverse

1. Manual valve lever improperly adjusted.
2. Cable linkage adjustment.
3. Reverse clutch piston stuck.
4. Reverse clutch plates worn out.
5. Reverse clutch leaking excessively.
6. Blocked reverse clutch apply orifice.

Improper Shift Points

1. Incorrectly adjusted carburetor-to-transmission linkage.
2. Incorrectly adjusted TV valve.
3. Governor defective.
4. Rear pump priming ball stuck.

Oil Forced Out of Filler Tube

1. Oil level too high causing planet carrier to run in oil and cause foam.
2. Oil pick-up pipe split or not sealed.

Unable To Push Start

1. Rear pump drive gear not engaged with drive pins on planet carrier hub.
2. Rear pump defective.
3. Rear pump priming ball not seating.

TRANSMISSION SHIFT POINT

Upshifts	M.P.H.
Minimum throttle	10-12½
Full throttle	41-47
Part throttle	34-41
Downshifts	**M.P.H.**
Closed throttle	8-12
Full throttle	38-44
Part throttle	23-30
Manual low	41-46

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

AXLE DESCRIPTION

The Corvair rear axle is of the straddle-mounted hypoid type which embodies a differential carrier mounted rigidly to the engine; no rear axle housing is used, Figs. 1 and 2. Independently suspended axle shafts are attached to universal joints which, in turn, are splined into the differential side gears.

A hollow shaft is used with the drive pinion to permit passage of the engine output shaft forward to the transmission. To permit the axial hole in the pinion shaft, the drive pinion and gear are two pieces coupled together. The drive pinion shaft is directly connected to the transmission output member. Preloaded tapered roller bearings support the drive pinion at fore and aft locations in the differential carrier. The ring gear is bolted to the differential case which is mounted on preloaded tapered roller bearings on each side of the differential carrier.

Components of the differential assembly are conventional with the exception of the side gears which have integral elongated splined hubs which project to the outboard extremity of the differential case and cover to receive the axle shaft universal joints.

Fig. 2 Powerglide transmission rear axle

AXLE SHAFT, BEARING & U-JOINT

Removal

1. Remove wheel and brake drum.
2. Unfasten bearing retainer from backing plate (four nuts accessible through hole in axle shaft flange).
3. Pull backing plate outward slightly then push it back onto the control arm studs to break away from the

Fig. 3 Axle shaft bearing

bearing retainer. The axle shaft can now be pulled outward sufficiently to free the U-joint splines from the differential side gears.

4. Remove U-joint from axle shaft (4 nuts from U-bolts).
5. Remove yoke from axle shaft.

Axle Shaft Bearings, Replace

1. Place axle shaft in a press with

Fig. 1 Three speed transmission rear axle

Fig. 4 Axle shaft components

Fig. 5 Removing side bearing adjusting sleeve

Fig. 7 Removing pinion from carrier

puller plate below the puller ring, Fig. 3.
2. Remove oil deflector, bearing and puller ring.
3. To install, place a new puller ring, bearing and oil deflector on axle shaft. *To prevent damaging bearing during installation of the new parts, place the old puller ring with its flat side against the bearing inner race and then press the puller ring and bearing onto the axle shaft.*
4. Remove old puller ring and install oil deflector.

Installation, Fig. 4

1. Insert axle shaft through lower control arm and install U-joint yoke on splines of axle shaft. It may be necessary to lightly tap yoke onto splines if original pieces are being installed. *When assembling new pieces for the first time, it is good practice to assemble and disassemble the yoke to the axle shaft with a press to ease the assembly of the pieces in the vehicle.*
2. Secure U-joint flange to axle shaft.
3. Attach U-joint to yoke on shaft with U-bolts.
4. With bearing retainer holes lined up with control arm studs, insert U-joint splines through seals in side bearing adjusting sleeves and index with side gear splines.
5. Secure bearing retainer to brake backing (4 nuts) via access hole in axle shaft flange.
6. Position brake drum control arm studs and secure wheel and drum.

Fig. 6 Removing pinion adjusting sleeve

Fig. 9 Pinion depth shim selection gauges

Fig. 8 Differential carrier

SIDE BEARING SLEEVE SEAL

The side bearing adjusting sleeve seal may be replaced while installed in the vehicle. Remove the U-joint from the side bearing adjusting sleeve. Pry out the seal, then install the new seal using any flat object as a driver as the seal mounts flush. *Seal lips must be inward.*

DIFFERENTIAL CARRIER

For removal and installation of the differential carrier, refer to the *Power Train Section.*

Disassemble Carrier

1. Loosen lock tab and remove speedometer driven gear.
2. Remove differential carrier cover.
3. Remove side gear adjusting sleeves, Fig. 5.
4. Remove pinion adjusting sleeve, Fig. 6.
5. Remove pinion drive gear with bearings attached, Fig. 7.
6. Remove differential from carrier by shifting differential to one side of carrier and then turning 90 degrees in order to remove via the cover hole in carrier.

Inspection

1. Inspect all bearing cups, races and rollers for damage and wear, especially large end of rollers as this is where wear is most evident on taper roller bearings. *The rear axle pinion bearings are of the preloaded type, and the natural wear pattern is a slightly frosted condition with occasional slight scratches on races and rollers. This does not indicate a defective bearing.*
2. On Powerglide axles, inspect oil seal in stator support and at converter hub for evidence of wear or damage.
3. Inspect pinion splines for evidence of excessive wear.
4. Inspect ring gear and pinion teeth for scoring, chipping or cracking.
5. Check fit of differential side gears in case.
6. Check fit of side gear and U-joint shaft splines.
7. Inspect differential pinion shaft for scoring or evidence of excessive wear.
8. Inspect differential carrier for cracks or crossed threads.

Fig. 10 Ring gear contact patterns

Fig. 11 Drilling side bearing adjusting sleeves for bearing race removal

AXLE REPAIRS

For Three Speed and Powerglide Axles

Note—Repairs required on three speed axles only, and those for Powerglide axles only are outlined further on. Refer to Fig. 8 for relationship of parts.

Pinion and Bearing, Replace

When it becomes necessary to replace pinion bearings and/or ring gear and drive pinion, it is necessary to re-establish the pinion mounting distance.

Pinion bearings may be removed with the aid of a press. It will be noted that a shim or shims are used between the pinion rear bearing and pinion. To determine the shim thickness to be used when installing new parts special gauges are required. Fig. 9. Lacking this equipment, check the ring gear contact pattern as shown in Fig. 10. To do this the differential carrier must be assembled. If a change is indicated, disassemble the parts and change the shimming as required to obtain the proper tooth contact pattern. Shims are available in thicknesses of .006, .009, .012, .015 and .018".

Pinion Front Bearing Race

Remove the old race with a punch. On Powerglide models it is necessary to remove the seal. Install a new race in the pinion adjusting sleeve using a suitable driver to push the race in place. Install a new seal on Powerglide units.

Fig. 12 Sealing drilled holes in adjusting sleeve with lead balls

Fig. 13 Differential assembly

Fig. 14 Installing ring gear on differential case and cover, using improvised guide pins

Side Bearing Adjusting Sleeve Bearing Race

1. Punch mark the side bearing adjusting sleeve at two places $\frac{9}{16}''$ outboard from the seal bore 180° apart, Fig. 11.
2. Using a $\frac{3}{16}''$ or smaller drill, drill through the adjusting sleeve at the punch mark locations until the drill is stopped by the bearing race.
3. Drive out the bearing race with a small pin punch.
4. Install a new bearing race in the sleeve with a suitable flat plate as a driver until the bearing race is flush.
5. Seal the drilled holes by using lead balls of at least .225″ diameter, Fig. 12. Balls of this type are commercially available for carburetor repair kits.

Differential Overhaul

Disassemble the differential as suggested by Fig. 13. To remove the differential pinions after the case has been separated, drive out the roll pin securing the differential pinion shaft to the case. *Before separating the differential case halves, punch mark the rim of both halves so that they may be attached in the original position, Fig. 14.* When securing the ring gear to the case, tighten all bolts to a torque of 40-60 ft. lbs. in a criss-cross pattern.

Fig. 15 Installing pinion rear oil seal in stator shaft

REPAIRS ON 3 SPEED TRANS. AXLES ONLY

Clutch Release Bearing Shaft Seal

Remove split ring and old seal from clutch release bearing shaft by prying out with a punch. Install the new seal, open side inward, using a suitable socket (¾″) and socket extension. Drive seal until it bottoms, then install split ring in clutch release bearing shaft.

Clutch Release Bearing Shaft and/or Pinion Bearing Rear Race

1. Place differential carrier in arbor press and press out shaft and race.
2. If a new shaft is being installed, first install the inner seal. Install a new seal ring in groove on outer diameter of bearing shaft and lubricate with vaseline.
3. Support differential carrier only on boss at clutch release bearing location with a suitable cylinder; then place bearing race on shaft and press both into differential carrier. Press until cup is flush with adjacent surface inside carrier.

REPAIRS ON POWER-GLIDE AXLES ONLY

Pinion Shaft Front Oil Seal and/or Converter Hub Oil Seal

The pinion shaft front oil seal and the converter hub oil seal are located diametrically opposite fore and aft. respectively, in the differential carrier.

Remove the oil seal by prying out with a punch or similar tool. Coat outer diameter of new seal with a non-hardening sealer and install seal. The converter hub seal is mounted flush. A special driver is available to install the pinion seal. A stop is provided on this driver which insures the seal being installed to the proper depth. This same driver (J-8340) is also used to drive the converter hub seal.

Pinion Shaft Rear Oil Seal

Drive out the old seal with a pin punch inserted through access hole in stator shaft. Install new seal as shown in Fig. 15 until it bottoms.

Pinion Shaft Bushing

Remove old bushing from inside diameter of pinion shaft using a chisel or other suitable tool. Use care not to damage the bushing mating surfaces in pinion shaft during removal.

Install new bushing with a suitable driver. Special tool J-8333 is available for this operation; it has a stop provided thereon to press the bushing to the proper depth.

Fig. 16 Installing stator shaft and pinion rear bearing race

Stator Shaft and/or Pinion Rear Bearing Race

1. Remove stator shaft and pinion bearing cup from carrier by placing carrier in a press and pressing downward on end of stator shaft. Replace parts removed.
2. Install seal ring in groove on outside diameter of stator shaft and lubricate with vaseline. *Outer diameter seal is not used on later production stator shafts.*
3. If a new stator shaft is being installed, it will be necessary to install a new pinion rear oil seal as previously described.
4. Align notch in stator shaft, Fig. 15, with drain back passage boss in differential carrier. Place bearing race on stator shaft and press race and shaft into housing, Fig. 16. *Carrier must be supported only at stator shaft boss for this operation.*

ASSEMBLE DIFFERENTIAL CARRIER

1. Referring to Fig. 8, insert differential into carrier with side bearing cones installed on differential hubs.
2. While differential is loose in carrier, insert pinion into carrier through cover hole. Then engage pinion with ring gear and carefully position pinion rear bearing in race. On Powerglide models, care must be used not to damage seal at this location when pinion is installed.

3. Install new O-ring seals in side bearing adjusting sleeves. Coat adjusting sleeve threads with a non-hardening pipe thread compound. Loosely install sleeves in carrier with side bearings positioned in sleeves.
4. On Powerglide models, install a new O-ring seal in pinion adjusting sleeve. Position pinion so that its front bearing will pick up the bearing race in sleeve and loosely install sleeve in carrier. Use care not to damage seal lips when inserting pinion shaft over adjusting sleeve.
5. Tighten both side bearing adjusting sleeves and pinion adjusting sleeve to the point of contact between bearings and races. At this point, there should be no preload on any of the bearings and ring gear and pinion backlash should be just enough so that the pinion and differential can be rotated easily and smoothly. The assembly is now ready for ring gear and pinion adjustment. *This adjustment, as well as checking ring gear and pinion backlash and other differential case operations is described in the Rear Axles Chapter.* Also refer to Fig. 10.

MASTER CYLINDER, REPLACE

1. Disconnect hydraulic lines from outlet end of cylinder.
2. Remove pedal return spring.
3. Unfasten 3 mounting nuts from dash wall and remove cylinder.

Suspension and Steering Section

SUSPENSION ADJUSTMENTS

Front Wheel Bearings

1. Raise car and remove cotter pin from spindle.
2. Tighten spindle nut to 100 inch lbs. (6 to 7 ft. lbs.) while rotating wheel.
3. Back off nut one flat (1/6 turn).
4. Insert cotter pin if slot in nut and hole in spindle align. If not, back off an additional ½ flat or less and insert cotter pin.
5. Spin wheel to make certain it rolls freely. *Wheel bearings should have .000" to .004" end play when properly adjusted.*

Front Wheel Camber

This is the first adjustment to be performed on the front suspension. The adjustment is made by means of shims between the upper control arm inner shaft and the front crossmember, Fig. 2. Although shims can be changed at either the front or rear attachment, it is important that the shimming be done equally so as to have no effect on caster. Adding shims at both front and rear of support shaft will decrease positive camber.

The procedure for adjustment is to loosen the upper support shaft-to-crossmember bolts and add or remove shims equally as required and retighten bolts. *It may be necessary to remove the wheel to secure these bolts.*

Fig. 1 Front suspension

Fig. 2 Camber shim

Front Wheel Caster

Caster is adjusted by turning the two nuts at the rear of the strut rod, Fig. 3. Lengthening this rod by turning the nuts increases caster while shortening the rod decreases caster.

Due to manufacturing tolerances, it is possible to "run out" of threads on the strut rod or cause the front coil spring to be cocked in its seat and rub the spring tower. Only when this happens is it permissible to shim unevenly at the upper control arm. However, if this is the case, camber must be rechecked.

Front Wheel Toe-In

1. Set steering gear on high point, with "saw cut" in steering shaft coupling at 6 o'clock position and steering wheel positioned for straight ahead driving.
2. Loosen clamp bolt at each end of each tie rod individually and adjust toe-in to specifications. Tighten clamp bolts and remove equipment.

Rear Wheel Toe-In

Due to the design of this independently sprung rear axle and suspension, it will be necessary to check and adjust rear wheel toe-in. *If drive on type equipment is used, reverse the vehicle and back it into position. Toe-in will be read as toe-out when vehicle is backwards because readings will be taken from the rear of the tires rather than the front. A tram may also be used in a similar procedure as that used on the front wheels except both sides will be adjusted at the same time. It must be pointed out, however, that since the wheels are adjusted by adding or removing shims at the front edge of the transmission, both wheels are adjusted at the same time.*

Fig. 3 Caster adjustment

A $\frac{1}{16}$" shim added to each side will increase toe-in. Removal of a $\frac{1}{16}$" shim from each side will decrease toe-in. Shims must be added or removed in pairs so that there is always the same number at each point.

Toe-in should be 0" or minus ¼" per wheel. Due to manufacturing tolerances and parts "stack-up" it is possible to have toe-out on one wheel and toe-in on the opposite wheel. In this case, adjust the suspension to bring the wheel with the toe-out as close to specifications as possible but not letting the opposite wheel go out of specifications. For example, if one wheel toes-out by ¼", then the opposite wheel must toe in enough to give 0" to¼" overall toe-in.

Rear Wheel Camber

Rear wheel camber should be 1½° positive (plus or minus ½°). There is no provision for adjustment of this item and it is provided as a checking specification only.

If camber is not within limits, either the crossmember is out of alignment with the body or has become distorted due to collision, etc., or else the control arm has become distorted, bent, etc.

CHECKING BALL JOINTS FOR WEAR

Upper Joint

The upper joint is checked for wear by checking the torque required to rotate the ball stud in the control arm.

1. Jack up under lower control arm at outer end and remove wheel.
2. Remove stud from steering knuckle.
3. Raise control arm to clear knuckle.
4. Install nut on stud and turn stud with a torque wrench. This should be a minimum of 2 ft. lbs. *If excessive wear is indicated, both upper and lower joints should be replaced.* If a tight joint is suspected, 5 ft. lbs. is the maximum allowable torque with the joint well lubricated.
5. Reassemble and lower car to floor.

Lower Joint

To check lower joint for wear, remove cotter pin and, with prick punch, mark nut and stud to identify relative location later. Tighten stud nut to original position with a torque wrench. If reading is less than 45 ft. lbs., stud may have been loose in steering knuckle and replacement of both lower joints is recommended.

FRONT END REPAIRS

In servicing the front suspension, it will be desirable to raise the car on a hoist and the suspension allowed to swing free. If a twin post hoist or similar equipment is used, support the front of the vehicle at the forward end of the body side rail extension (each side) with jackstands and lower front of hoist.

Shock Absorber, Replace

1. With vehicle supported and front end hanging free, remove upper attaching nut, cup washer and grommet.
2. Remove two lower attaching bolts.
3. Withdraw shock absorber through lower control arm.
4. Reverse above procedure to install, extending shock absorber shaft to its full length to facilitate installation.

Coil Spring, Replace

1. Raise vehicle and allow front control arms to swing free.
2. Remove shock absorber.
3. Remove strut rod nuts (pressed in).
4. *Loosen but do not remove* lower control arm inner pivot nut.
5. Place jackstand under inner end of control arm under bushing.
6. Remove control arm pivot nut and tap out pivot pin.
7. Lower hoist or jackstand until spring is free and take it out. *A bar placed through control arm and into spring tower will retain spring and keep it from slipping until free. Otherwise, keep clear of suspension until all compression is removed from spring.*

Reverse above procedure to replace the spring. When installing, place rubber spacer in place on top of spring and secure it friction tape. Step in spacer must contact end of spring.

The tension in the strut rod is due to the rubber grommet at the opposite end of the rod. Do not touch the large nuts at the grommet end as these control caster adjustment, Fig. 3.

Fig. 4 Rear axle positioning for rear spring removal

Fig. 5 Steering gear worm nut and ball circuits

Lower Control Arm and Ball Joint, Replace

To remove these parts, take out the coil spring as outlined above. Then remove lower ball joint nut and tap control arm to remove it and joint from knuckle. Use a suitable wrench to remove self-tapping joint from lower control arm. Reverse above procedure to install parts removed.

Upper Control Arm and Ball Joint, Replace

With wheel removed, remove nut from upper ball joint stud. Remove stud from knuckle. Remove two nuts retaining upper control arm shaft to crossmember. *Note number of shims at each bolt.*

To remove ball joint from control arm, cut off rivet heads, being careful not to enlarge holes in control arm. Tap out rivets and remove joint from control arm.

Install new joint, using special alloy bolts and nuts furnished with new ball joint. Tighten nuts to a torque of 20-25 ft. lbs.

When control arm has been installed, bounce front end of car to centralize bushings and tighten cross shaft bolts to a torque of 35-40 ft. lbs.

If ball joint was replaced or if proper number of shims were not reinstalled, recheck camber and caster.

REAR SUSPENSION REPAIRS

Shock Absorber, Replace

The attachment of the rear shock absorber is identical to the mounting of the front suspension. However, the rear shock absorber holds all of the rear spring compression. For this reason, the weight of the vehicle must be resting on the tires.

Place the car on a drive-on type hoist, frame contact hoist or place jack stands under the body at each side rail, just forward of the rear wheel openings. The

body should be raised high enough so that the wheels hang free and a floor jack can be placed under the tire. With a second jack, raise tire so that it is in normal position. This will allow shock absorber to be removed without interfering with the floor.

Coil Spring, Replace

1. Raise vehicle by body side rails so that control arms may swing free. Vehicle must be raised enough to allow a rolling floor jack to be placed under brake drum.
2. Loosen control arm cross shaft bolts (in ends of shaft). Remove bolt that holds brake hose bracket to underbody. It may also be necessary to disconnect and plug fuel line and heater fuel supply line (on left side only). Remove wheel. Replace nuts on studs to hold drum in place.
3. Position axle as shown in Fig. 4 to allow axle shaft and control arm to swing down far enough to remove spring.
4. Place rolling jack under brake drum. Raise jack slightly to place a light load on spring. Remove shock absorber.
5. Carefully lower floor jack until spring is free. *Do not remove or lower jack too far as this places too much strain on axle shaft and brake hose.*
6. Reverse above procedure to install and lower vehicle to floor. Bounce rear end several times and tighten cross shaft bolts to a torque of 45-55 ft. lbs.

Lower Control Arm, Replace

1. Remove coil spring as outlined above.
2. Before removing floor jack from under drum, support control arm with a jack stand without placing strain on brake hose.
3. Remove brake drum.
4. With a screwdriver, shift upper end of a brake shoe onto the brake anchor, which will allow axle flange plate and axle shaft to be pulled out past parking brake strut.
5. Remove backing plate nuts.
6. Pry between axle flange plate and backing plate until axle shaft and U-joint can be pulled out of case.
7. Remove U-joint bolts.
8. Remove bolt from end of axle shaft.
9. Remove U-joint yoke and withdraw axle shaft.
10. Remove backing plate from lower control arm studs. Tie backing plate up to crossmember.
11. Unfasten control arm from crossmember (4 bolts). A parking brake cable is also attached to two of these bolts. Remove control arm.
12. Reverse above procedure to install parts removed.

Fig. 7 Exploded view of steering gear

HORN SOUNDER & STEERING WHEEL

1. To remove, first pry out horn button. Remove three screws attaching receiver cup and bushing spacer to steering wheel. Remove flat spring.
2. Remove nut from steering shaft and use a puller to remove wheel, being careful not to lose spring or seat located under wheel.
3. Reverse above procedure to install, making sure that mark on steering shaft lines up with mark on steering wheel hub.

STEERING GEAR

Adjustments

Before attempting steering gear adjustments in an attempt to correct such conditions as shimmy, loose or hard steering or road shocks, make a careful check of front end alignment, shock absorbers, wheel balance and tire pressure for possible causes.

Only two adjustments are possible on the steering gear, Fig. 5, but they must be made in the following manner, step by step, in the order given.

1. Separate steering connecting rod from pitman arm.
2. Loosen lash adjuster screw lock nut, Fig. 6, and turn screw out of gear case far enough to remove all high spot preload.
3. Rotate steering wheel to end of travel, then back it exactly halfway.
4. Hook a spring scale to rim of steering wheel and turn wheel by pulling at ring of scale. It should require a pull of 7 to 11 ounces to keep wheel in motion. If not within these limits, adjust worm bearing preload as follows:
5. Turn worm bearing adjuster, Fig. 5, in the proper direction to increase or decrease preload as required; turning adjuster to right increases preload.
6. If there is a feeling of roughness or a wide variation of scale readings at different points during rotation of steering wheel, the gear should be disassembled and inspected for worn or damaged parts.
7. With worm bearing preload properly adjusted, turn lash adjusting screw into gear case until light contact is felt between sector gear and ball nut when steering wheel is in the straight ahead position, Fig. 6.
8. While holding adjusting screw in position with screwdriver, snug lock nut against gear case. Position the spring scale on steering wheel rim and rotate wheel through high point area (¼ turn each way from center of gear travel). Scale reading should be 18 to 24 ounces.
9. Repeat adjustment procedure until reading falls within this range, remembering that turning adjusting screw *in* increases preload. Tighten adjusting screw lock nut before each scale reading.
10. Connect steering rod to pitman arm and torque nut to 40-60 ft. lbs.

Steering Gear, Replace

1. Disconnect pitman arm from pitman shaft.

Fig. 6 Steering gear pitman (sector) shaft

2. Unfasten steering gear from frame (3 bolts).
3. Unfasten steering shaft coupling (3 bolts) and slide steering gear forward and down, removing it from car.
4. Reverse above procedure to install steering gear.

Steering Gear, Overhaul

1. Referring to Fig. 7, turn pitman shaft adjuster a few turns counterclockwise. This will remove load from worm bearings caused by the close meshing of rack and sector teeth.
2. Turn worm bearing adjuster counterclockwise a few turns.
3. Unfasten and remove side cover and pitman shaft. *If sector does not clear opening in housing easily, turn worm shaft by hand until sector will pass through opening in housing.*
4. Remove worm bearing adjuster, lock nut and lower bearing from housing.
5. Draw worm shaft and nut assembly from housing. Remove upper bearing. *Use care that ball nut does not run down to either end of worm. Damage will be done to ends of ball guides if nut is allowed to rotate until stopped at end of worm.*
6. Unscrew lash adjuster from side cover. Slide adjuster and shim out of slot in end of pitman shaft.
7. If the ball bearing nut is perfectly free with no indication of binding or tightness when rotated on worm, do not disassemble. However, if these conditions exist, remove clamp and draw guide out of nut. Turn nut upside down and rotate worm shaft back and forth until all 36 balls have dropped out of nut. With balls removed, nut can be pulled endwise off worm.
8. Reverse above procedure to assemble the steering gear and adjust as outlined previously. When assembling lash adjuster, place shim in slot in end of sector shaft. Check end clearance which should not exceed .002. For adjusting purposes, shims of four thicknesses (.063, .065, .067 and .069″) are available.

Instruments & Windshield Wiper

INSTRUMENT CLUSTER

1. Disconnect battery ground cable from battery.
2. Remove the connectors from back of instrument cluster and pull harness out of retaining clips on back of cluster.
3. Disconnect speedometer cable.
4. Remove light switch and from beneath dash remove nut attaching lighter (if equipped) and withdraw lighter.
5. Lower mast jacket and steering wheel assembly from instrument panel or remove steering wheel on 3-speed models or steering wheel and turn signal housing on automatic transmission models to give clearance for cluster removal.
6. Remove cluster attaching screws and remove the cluster, instrument center panel and seal by pulling straight out, turning slightly to clear transmission range selector.
7. Remove two harness clips from back of cluster.
8. Remove screws attaching the cluster back to the cluster.
9. Remove instruments and speedometer as required.

WINDSHIELD WIPER

1. Remove retainer securing drive link to wiper motor drive arm.
2. If equipped with a washer, note location of washer hoses to wiper motor, then remove hoses from motor from inside front compartment. Also remove electrical connectors from motor.
3. Remove screws securing motor to the body and remove motor.
4. To install, reverse above procedure. *It is important that the three screws attaching motor be fully tightened so that the sleeves surrounding the screws bottoms to prevent "floating" of the motor.*

①—Fit rings in tapered bores for clearance listed in tightest portion of ring travel.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness. On aluminum engines, none of these bolts, including cylinder head bolts, should be re-tightened with the engine at normal operating temperature.

①—For permanent type anti-freeze.
②—For alcohol type anti-freeze.
③—Add one quart with filter change.
④—Engine and converter have a combined oiling system which requires 10 quarts of oil. An additional quart is necessary when replacing oil filter element.
⑤—Powerflite 10 quarts. Torqueflite 9 quarts.
⑥—Station wagons, 22; all others, 20.
⑦—Suburban 22 gals.
⑧—14 lbs. with air conditioning.
⑨—Suburbans 21 gallons.
⑩—16 lbs. with air conditioning.
⑪—Golden Comando 3¼ pints.
⑫—Suburbans 21½ gallons.

①—For each 10° rise in temperature subtract .04 volt; for each 10° drop in temperature add .04 volt. Temperature is checked with a thermometer 2 inches from installed voltage regulator cover.
②—Current draw at 12 volts while turning rotor shaft by hand.
③—Plus or minus 3 amperes. If output is low, stator or rectifier is shorted.
④—At 2200 RPM there should be a voltage increase of .2 to .7 volt.

GENERATOR AND REGULATOR SPECIFICATIONS

★To polarize generator, reconnect the leads to the regulator; then momentarily connect a jumper wire from the "Arm" to the "Bat" terminals of the regulator.

Engine Section

ENGINE MARKINGS

The letter "A" immediately following the engine number indicates .020″ oversize cylinder bores.

The letter "B" immediately following the engine number indicates .010″ undersize crankshaft journals.

The letters "AB" immediately following the engine number indicates .020″ oversize cylinder bores and .010″ undersize crankshaft hournals.

A maltese cross ⅜″ high stamped on engine numbering pad indicates a crankshaft that has one or more connecting rods and main bearings finished .001″ undersize.

A diamond shaped mark stamped on engine numbering pad indicates that all valve lifter bodies are .008″ oversize.

ENGINE, REPLACE

Dodge

In addition to the usual items such as fuel lines, linkage, propeller shaft, etc., it is necessary to perform the following operations:

1. Remove hood and battery.
2. Remove radiator and exhaust pipes.
3. On 1953-55 V8, support transmission and remove engine rear support and crossmember. Remove front support bolts and lift engine from chassis.
4. On 1953-59 Sixes, remove transmission, front and rear engine supports and lift out engine.
5. On 1956-57 V8 and 1958 Red Ram, support transmission and remove rear engine support crossmember. Remove front supports and lift engine and transmission out of car.
6. On 1958 Super Red Ram and all 1959-62 V8's, support rear of engine and remove engine rear support crossmember. Remove transmission. Remove engine front mounting nuts and lift engine out of chassis.
7. On 1960-62 Six, support rear of engine and remove rear engine support crossmember. Disconnect converter from flex plate and remove transmission and converter as an assembly. Remove front engine mounting bolts and lift engine out of chassis.

Plymouth

In addition to the usual items such as fuel lines, linkage, propeller shaft, etc., the following operations must be performed:

Slant Six engine

1. Remove hood and battery.
2. Remove radiator.
3. Remove exhaust pipes.
4. On 1953-59 Six, remove transmission as outlined further on. Then remove crankcase breather pipe and front and rear engine support bolts. Raise engine, remove front engine support and lift out engine. When installing engine, before tightening engine support bolts, loosen exhaust pipe support brackets and allow engine to run a few seconds so it will align itself and then complete tightening.
5. On 1955 V8, if transmission is to be removed, place a jack under transmission and remove engine rear crossmember. Lower and remove jack under transmission and lift engine out of chassis towards left front fender.
6. On 1956-62 V8 except Commando, remove crossmember-to-transmission bolts. Place a jack under transmission and remove crossmember rear engine support. Remove engine front support and lift engine out of chassis.
7. On 1958-62 Commando engines, support rear of engine and remove engine rear support crossmember. Then remove transmission and lift engine out of chassis.

1955-59 Six

Fig. 1 Cylinder head tightening sequence. Slant Six

8. On 1960-62 Six, support rear of engine and remove engine rear support crossmember. Disconnect converter from flex plate and remove transmission and converter assembly. Remove engine support and front engine mounting bolts and lift engine out of chassis.

CYLINDER HEAD

1960-62 Six

1. To remove head, drain cooling system.
2. Remove carburetor air cleaner and fuel line.
3. Disconnect accelerator linkage.
4. Remove vacuum control tube at carburetor and distributor.
5. Disconnect spark plug wires, heater hose and clamp holding by-pass hose.
6. Disconnect heat indicator sending unit wire.
7. Disconnect exhaust pipe at manifold.
8. Remove intake and exhaust manifold and carburetor as a unit.
9. Remove outlet vent tube and rocker arm cover.
10. Remove thermostat housing and thermostat.
11. Remove rocker arms and push rods.
12. Remove head bolts and lift off heads.
13. Install head in reverse order of removal and tighten bolts in the sequence shown in Fig. 1, and to the torque listed in the *Engine Tightening* chart. *When installing the manifolds, loosen the three bolts holding the intake manifold to the exhaust manifold. This is required to maintain proper alignment.* Install manifolds and carburetor as a unit with the cup side of the conical washers against the manifolds. Tighten the nuts to 10 ft. lbs. Then

Fig. 2 Cylinder head tightening. 1955-59 Six

Internal engine parts. Slant Six

Dodge 1955-58 engine with forged rocker arms and one rocker shaft for each bank

V8-350, 361, 383 with stamped steel rocker arms

Dodge 1955-57 engine with two rocker arm shafts for each bank, exhaust valve seat inserts and two springs for each valve

Fig. 3 Cylinder head tightening. 1955-57 and 1958-62 V8-241, 259, 270, 277, 301, 303, V8-318, 326

tighten the three bolts holding the intake manifold to exhaust manifold to 15 ft. lbs.

1955-59 Six

1. Drain cooling system.
2. Remove fuel line from carburetor.
3. Remove carburetor air cleaner.
4. Remove carburetor.
5. Remove upper radiator hose, spark plugs, engine heat indicator unit and cylinder or capscrews.
6. Lift cylinder head from block, using lifting hooks in two of the spark plug holes. Do not use a screwdriver, chisel or other sharp instrument to drive between the head and block to loosen the head as damage may result.

Installation

Before the cylinder head is installed, make certain that all dirt and carbon is removed from both the head and block.

If possible, use a torque wrench when tightening cylinder head nuts or capscrews. Uneven or excessive tightening may distort cylinder bores, causing compression loss and excessive oil consumption.

Tighten cylinder heads in the order shown in Fig. 2, tightening a little at a time in the proper sequence about three times around before final tightening to the torque values given in the *Engine Tightening* chart. After the engine has warmed up to operating temperature, recheck the nuts and adjust torque as required.

Plymouth 1955-58 V8-241, 259, 270, 277, 301, 303

1. Remove intake manifold and rocker arm covers after draining cooling system.
2. On engines with hydraulic valve lifters, remove the rocker arm assemblies and lift out the push rods.
3. On engines with mechanical valve lifters, back out each tappet adjusting screw until the screw is clear of the push rod socket. Then slide the rocker arm to one side, compressing the rocker shaft spring, and

Fig. 4 Cylinder head tightening. 1958-62 V8-350, 361, 383

Engine lubrication. Dodge V8-241, 270. Plymouth V8-241, 259, 270

Engine lubrication. Dodge and Dart V8-318, 326. Plymouth V8-277, 301, 318

lift out the push rod. Repeat this procedure for all other push rods. *Place push rods in a suitable rack in order that each rod can be reinstalled in its original position.*

4. Remove cylinder head bolts and lift off cylinder head.
5. When installing the heads, tighten all bolts evenly the first time around to a torque of 35 lb. ft. Then repeat the tightening procedure in the sequence shown in Fig. 3 to the specified torque of 85 lb. ft. Run the engine until normal operating temperature is reached and recheck the torque.

1959-62 V8-318, 326

1. Drain cooling system.
2. Remove carburetor air cleaner.
3. Disconnect pump-to-carburetor fuel line.
4. Remove distributor vacuum tube.
5. Remove generator or alternator.
6. Disconnect throttle linkage at carburetor.
7. Remove distributor cap, coil wires, heat indicator sending unit wire and heater hoses at engine.
8. Remove spark plugs and cables.
9. Remove engine ventilator pipe.
10. Remove intake manifold, carburetor and coil as an assembly.
11. Remove exhaust manifolds.
12. Remove rocker arm covers.
13. Remove cylinder heads and push rods.
14. Reverse order of removal to install heads and tighten bolts in the sequence shown in Fig. 3.

1958-62 V8-350, 361, 383

Rocker arm assemblies can be removed without disturbing the cylinder heads or cooling system. To remove the heads, proceed as follows:

1. Drain cooling system, remove air cleaner, fuel line from pump and carburetor, distributor vacuum tube and generator or alternator.
2. Disconnect throttle linkage at carburetor, distributor cap, coil wires, heat indicator sending unit wire and heater hoses at engine.
3. Remove spark plugs and cables, and engine ventilating outlet pipe.
4. Remove intake manifold, carburetor and coil as an assembly.
5. Remove exhaust manifolds.
6. Remove cylinder head covers and spark plug cable support brackets.
7. Remove rocker shaft assemblies. *Do not remove bolts from end brackets.*
8. Remove push rods and valve lifter chamber cover.
9. Remove attaching bolts and lift off heads.
10. Reverse the foregoing procedure to install the heads and tighten the bolts in the sequence shown in Fig. 4 to a torque 70 lb. ft. Tighten intake and exhaust manifold bolts to to a torque of 30 lb. ft.

1955-57 & 1958 Red Ram

1. Remove air cleaner.
2. Remove generator.
3. Disconnect fuel and vacuum lines at carburetor.
4. Disconnect carburetor kickdown switch (if equipped).
5. Disconnect linkage at carburetor.
6. Disconnect coil wires.
7. Remove heat indicator bulb.
8. Disconnect heater hose.
9. Remove intake manifold, carburetor and coil as a unit.
10. Disconnect exhaust manifold-to-exhaust pipe flange.
11. Remove bolts holding water pump housing to cylinder heads.
12. Remove distributor cap and cables.
13. Remove rocker arm assemblies.
14. Lift out push rods.
15. Remove cylinder heads.
16. Reverse removal procedure and tighten the heads in the sequence shown in Fig. 3.

VALVES, ADJUST

1960-62 Six

Before the final valve lash adjustment is made, operate the engine for 30 minutes at a fast idle to stabilize engine temperatures. Before starting the adjustment, make two chalk marks on the vibration damper. Space the marks about 120 degrees apart (⅓ of circumference) so that with the timing mark the damper is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

Service Note

When adjusting valves in aluminum engines, run the engine until normal op-

Fig. 5 Rocker arm shaft assembly. V8-350, 361, 383

erating temperature is reached. Then remove the rocker arm cover. After the rocker cover has been removed, run the engine an additional five minutes at idle speed. Then adjust the valve clearance. It is necessary that the foregoing procedure be followed because of the different expansion characteristics of the metals involved.

1955-59 Six

Valve tappets should be adjusted with engine running and at normal operating temperature. It is important that the clearances given in *Valve Chart* be maintained to insure satisfactory engine performance. If the car is driven at continuous high speeds, an additional .002″ clearance for exhaust tappets is desirable.

If the car being serviced is one wherein the valves are not accessible when the hood is raised, proceed as follows:

1. Raise right front end of car and support it with a stand.
2. Remove right front wheel and splash shield access cover if one is provided.
3. Remove valve chamber covers.
4. With engine idling and warmed up to operating temperature, adjust the intake valves and then follow through by adjusting all exhaust valves.

V8s With Mechanical Lifters

Engines with mechanical lifters can be identified by the rocker arm adjusting screws. These screws are self-locking and when turning them during the process of adjustment they should indicate some resistance to turning (a minimum of 3 lb. ft. tension). If any screw turns too easily it should be replaced and, if necessary, the rocker arm as well.

Valve clearances should be set up after the engine is warmed up to operating temperature and to the clearances listed in the *Valve Specifications* table.

1960-62 Six ....E-I-E-I-E-I-I-E-I-E-I-E

ROCKER ARMS

Service Note

Some early 1956-58 and all 1959-62 V8-318 engines (distributor at rear of block) have rocker arm shaft brackets cast in the cylinder head. It is necessary, therefore, to remove the cylinder head when service is required on rocker arms and shafts.

1958-61 V8-350, 361, 383

Disassemble rocker shaft assemblies by removing bolts from support brackets and sliding brackets, rocker arms and spacers from the shaft, Fig. 5. Clean all parts *except the oilite spacers* in a suitable solvent. Keep oilite spacers soaked in engine oil until reassembled. Inspect all parts for excessive wear. Test shaft end plugs for evidence of leaks.

Install the rocker shafts so the oil holes are positioned as shown in Fig. 6. *It is important that the shafts be installed as indicated, otherwise excessive oil spray and improper lubrication of the valve mechanisms can result.*

Assemble rocker arms in pairs between brackets with an oilite spacer between the arms and with the push rod socket section of each arm close together rather than far apart. Install bolts through the brackets to hold the assembly together until ready to install on cylinder heads.

Fig. 6 Rocker arm shaft installation. V8-361 and 383 engines

Fig. 7 Top and bottom view 1955-57 Super Red Ram

1955-57 & 1958-62 V8-318, 326

Sludge and gum formation in the rocker arms and shafts, Figs. 7 and 8, will restrict the normal flow to the rocker arms and valves. Each time the assemblies are removed (see *Cylinder Heads*), they should be disassembled and thoroughly cleaned.

Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Inspect the shafts for wear. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When the assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves.

Check each push rod for a bent or damaged condition. If bent more than .020″, when checked with an indicator, replace the push rod. Do not attempt to straighten a bent rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

1960-62 Six

To remove rocker arms, take off head cover outlet tube, rocker arm cover and rocker shaft bolts and retainers. Lift off rocker arm and shaft assembly.

Clean all parts. Be sure the inside of the shaft is clean and the oil holes are open. The drilled hole in the bore of the rocker arm must be open to the trough and valve end of the arms. The trough also feeds oil to the adjusting screw and push rod. Assemble and install as follows:

1. Referring to Fig. 9, note flat on forward end of rocker shaft. The flat also denotes the upper side of the shaft. Rocker arms must be put on the shaft with the adjusting screw to the right side of the engine. Place one of the small retainers

Engine lubrication. 1955-57 with two rocker arm shafts for each bank

Engine lubrication. V8-350, 361, 383

on the one long bolt and install the bolt in the rear hole in the shaft from the top side.

2. Install one rocker arm and one spacer; then two rocker arms and a spacer. Continue in same sequence until all rocker arms and spacers are on the shaft.
3. Place a bolt and small retainer in front hole in shaft.
4. Place a bolt and the one *wide* retainer through the center hole in the shaft with six rocker arms on each side of center.
5. Install remaining bolts and retainers, separating the four pairs of rocker arms.
6. Locate assembly on cylinder head and position rocker arm adjusting screws in push rods.
7. Tighten bolts finger tight, bringing retainers in contact with shaft *between rocker arms*. Then tighten bolts to 30 ft. lbs.
8. After running engine to normal operating temperature, adjust valve lash to specifications. Complete installation of remaining parts removed.

Fig. 8 Layout of rocker arm parts. Early V8 engines

Fig. 9 Rocker arm and shaft assembly. Slant six

VALVES, REMOVE

1955-59 Six

After taking off the cylinder head as outlined previously, take off the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase, Fig. 10.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so that they

Fig. 10 Valve details. 1955-59 Six

Fig. 11 Compressing valve spring

can be identified as to the valve port from which they were removed.

V8's and Slant Six

Place the cylinder head on its side and with a suitable valve spring compressor, compress the valve spring and remove the valve locks, Fig. 11. Release the tool and remove spring retainer and spring. Remove any burrs or sharp edges on the valve stem before removing the cup seal and valve. As the valves are removed, keep them in a numbered board or rack in the same order as they were in the head so they will be in proper sequence for inspection and assembly, Fig. 12.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Figs. 13 and 14. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 12 Valves and related parts. Typical of all models

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is $\frac{1}{16}$", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valves, remove the springs and wash them with gasoline

Fig. 13 Checking valve spring installed height on engines with removable valve guides

Fig. 14 Checking valve spring installed height on engines with integral valve guides

Fig. 16 Showing drift with pilot extending into valve guide for removing and installing guides. Mark drift as shown to indicate depth to which the guide must be driven in. 1955-59 Six

or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available, Fig. 15. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Data* chart within 10 per cent should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

1960-62 Six

To check the length of the valve spring when installed, install the valve, spring retainer and locks (without the spring). With the locks seated in the retainer and the valve seated, the space between the spring seat on the cylinder head and the underside of the retainer should be $1\frac{5}{8}''$ to $1\frac{11}{16}''$. If more than $1\frac{11}{16}''$, use a $\frac{1}{16}''$ spacer under the spring when assembling.

VALVE GUIDES

1955-59 Six

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides carefully. The standard clearances are given in the *Valve Data* chart.

Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption. fouled spark plugs and poor low speed performance.

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace valve guides, the tool shown in Fig. 16 should be used. If not available, the old guides can be pulled out by using a suitable piece of pipe together with a long bolt and suitable washers.

After the new guides have been installed, they should be reamed, to provide the clearances given in the *Valve Data* chart.

Engines With Integral Guides

Valve guides in these engines are an integral part of the cylinder heads and, therefore, cannot be removed. For service, guide holes can be reamed oversize to accommodate one of three service valves with oversize stems (.005″, .015″ and .030″).

Test the valve guides for wear as shown in Fig. 17. Install a suitable sleeve over the valve stem to hold the valve at working height in the head. Attach a dial indicator having valve stem at right angle with edge of valve. Move valve to and from indicator. Total movement should not exceed .010″ on intake valves and .014″ on exhaust valves. If tolerance is excessive, ream guide holes and install valves with overside stems. Always use a .005″ reamer first, then (if necessary) a .015″ reamer and finally a .030″ reamer so the guides remain true in relation to the seat.

Fig. 15 Fixture for checking valve spring pressure

Engines With Removable Guides

Remove the old guides by driving them out through the top of the cylinder head. Drive the new guides is place by driving them up through the valve port opening. To determine how far the guides should be driven in, see Fig. 18.

When installing exhaust valve guides, make certain that the oil holes in the top of the guides are facing up.

After valve guides are properly installed, ream each guide so the inside diameter measures .374-375″, Fig. 18.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

If refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}''$, otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face, Fig. 19.

Inspect the valve seats in the block for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition, If new valve guides are required, they must be installed and reamed before refacing the seats if the equipment used for refacing the seats has a valve guide pilot.

Fig. 17 Measuring valve guide wear with dial gauge

The valve seat width after refacing should be a liberal $\frac{1}{16}''$ for intake seats but not more than $\frac{3}{32}''$ in any case. The width of exhaust seats should be $\frac{3}{64}''$ to a liberal $\frac{1}{16}''$.

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

VALVE SEAT INSERTS

1955-59 Six

Since these inserts are too hard to reface by ordinary valve grinding methods, a high speed grinder or special lapping equipment should be used to perform this operation. When using this equipment, be sure valve guides are clean and the valve guide pilot is a snug fit in order to assure a concentric finish. Finished seats should be checked with a dial indicator and runout should not exceed .001".

To remove an insert (if a suitable puller, Fig. 21, is not available) drill two holes at opposite sides of the insert, but not all the way through. Then cut through the undrilled portion with a sharp chisel and remove the two pieces.

To install a new insert, first remove all burrs and sharp edges from the seat recess. Then chill the new insert with dry ice to obtain maximum contraction and place it in the recess.

If a standard insert is too loose (less than .002" press fit) a .010" oversize seat is available. Before it can be installed, however, the recess in the block must be machined to fit the seat.

VALVE LIFTERS

1955-59 Six

Since these lifters are of the mushroom type operating in guide holes bored in the cylinder block, it is necessary to remove the camshaft in order to remove the lifters.

Fig. 19 Valve nomenclature

Follow instructions for removing the camshaft. Then remove the oil pan and take the lifters out through the bottom of the engine.

Lifters are furnished in oversizes of .001, .008, .030 and .060". When reaming the lifter guides for oversize lifters, the cylinder head and valves will have to be removed so that the reamer pilot can be inserted through the valve stem guide hole.

1960-62 Six

After taking off the rocker arm and shaft assembly, lift out push rods. The valve lifters may then be removed with a suitably long magnet rod. If the lifters cannot be removed with the magnet rod, a special tool (C-3661) may be used. Insert the tool through the push rod opening in the cylinder head and into lifter. Turn the handle to expand the tool in the lifter, then with a twisting motion remove the lifter from its bore. Place lifters in a board or rack with numbered holes since each lifter must be reinstalled in its original location.

Inspect the lifters for scores and the lower ends for pits and rough surfaces. Check crowned faces of lifters with a straightedge. If any negative crown (dish) is observed, the lifter should be replaced.

Service Note

Valve lifters in aluminum engines operate in machined bores and may be rebored to accommodate oversize lifters of .001", .008" and .030".

Fig. 18 Valve guide details. 1955-57 Super Red Ram

Fig. 22 Layout of flat valve type hydraulic lifter

HYDRAULIC LIFTERS

V8 Engines

Figs. 22, 23, 24 illustrate the types of hydraulic valve lifters used. See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Place one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be

Fig. 21 Valve seat insert puller

Fig. 23 Hydraulic valve lifter

Fig. 24 Layout of ball valve type hydraulic lifter

Fig. 26 Testing hydraulic valve lifter

removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

Removing Lifters

On the Super Red Ram engine the valve lifters can be removed through the push rod holes in the cylinder heads by the use of a tool of the type shown in Fig. 25, after removing the rocker shaft assemblies and push rods.

On 1955-57 and Red Ram engines the lifters may be removed after taking off the intake manifold. If the lifters are stuck in the bores due to carbon or varnish build-up, use a tool of the type shown in Fig. 25 and use a twisting motion to pull the lifter out of the bore. The sharp edge at the bottom of the lifter bore will shave the varnish and carbon deposits off the lifter as it is being withdrawn.

Servicing Lifters

Hydraulic plungers and bodies are not interchangeable. Therefore, it is advisable to work on one lifter at a time to avoid mixing parts. *Mixed parts will not function.*

In testing a lifter, secure a container deep enough to completely immerse the lifter assembly. Fill the container with clean kerosene. Remove the cap from the plunger and submerge the lifter. Allow the cylinder to fill with kerosene. Then remove the lifter and replace the cap.

Holding the lifter upright, insert the lower jaw of the pliers shown in Fig. 26 in the top groove of the lifter body. Engage the upper jaw of the pliers with the top of the plunger cap as shown. Check the leakdown by compressing the pliers. If the plunger collapses almost instantly, disassemble the unit, clean it again and retest. If the lifter still does not function satisfactorily, install a new unit, being sure to test the new one before installing it in the engine.

Fig. 25 Removing stuck hydraulic valve lifter

CHAIN CASE COVER

1955 V8

To remove the chain case cover on these engines, proceed as follows:

1. Drain cooling system and disconnect water hoses.
2. Remove generator and mounting bracket and fan belt.
3. Remove radiator.
4. Use a suitable puller to remove crankshaft pulley.
5. With a chain hoist fastened to the intake manifold, slightly relieve engine weight on front motor support. Then remove the four motor support bolts.
6. Remove fan blades and hub.
7. Remove bolts that hold water pump housing to the cylinder block and heads. Then lift water pump, housing, front motor support and insulator up and away from the engine.
8. Loosen the bolts that hold the oil pan to the cylinder block. Then drop the pan slightly to clear the chain case cover.
9. Disconnect fuel lines at fuel pump.
10. Remove fuel pump from chain case cover.
11. Unfasten chain case cover from cylinder block and pull the cover out and away from the block.
12. Replace the cover oil seal.
13. Reinstall the cover in the reverse order from which it was removed, being sure to guard against water and oil leaks.

Fig. 27 Special centering tool for chain case cover oil seal. 1955-59 Six

Fig. 28 Timing marks aligned for correct valve timing. V8s

Fig. 29 Timing marks aligned for correct valve timing. Slant Six

1958-62 V8-350, 361, 383

1. Drain cooling system.
2. Remove radiator, fan and belt.
3. Remove water pump and housing as an assembly.
4. Remove crankshaft bolt and pulley from vibration damper and remove damper with a puller.
5. Remove key from crankshaft.
6. Remove chain case cover and gasket. *Use extreme caution to avoid damaging the oil pan gasket; if damaged it will be necessary to remove the oil pan in order to install a new pan gasket.*

1956-57 V8

1. Disconnect water hoses.
2. Remove generator.
3. Remove radiator.
4. Remove retaining bolt and slide crankshaft pulley off end of crankshaft.
5. Remove fan blades and hub.
6. Remove water pump.
7. Loosen oil pan bolts and drop pan slightly to clear chain case cover.
8. Remove fuel pump.
9. Remove chain case cover.

1959-62 V8-318, 326

1. Remove radiator, fan and belt.
2. Remove water pump and housing as a unit.
3. Remove crankshaft pulley.
4. Remove key from crankshaft.
5. Remove fuel pump.
6. Remove chain case cover and gasket, *using extreme caution to avoid damaging oil pan gasket otherwise oil pan will have to be removed. It is normal to find particles of neoprene collected between crankshaft seal retainer and oil slinger.*

1960-62 Six

1. To remove cover, drain cooling system and remove radiator and fan.
2. Remove vibration damper with a puller.
3. Loosen oil pan bolts to allow clearance and remove chain case cover.
4. Reverse above procedure to install cover.

1955-59 Six

When installing the chain case cover on these engines, place a new gasket in the cover, then drive the oil seal in position, using a drift or a flat piece of metal slightly larger than the seal to assure a tight, even contact between the seal and its seat.

When fastening the cover, care must be used to center the seal on the crankshaft before tightening the cover screws. A special centering tool, Fig. 27, is available to make the installation. When using this tool, tighten the screws only enough to hold the cover in place. Then insert the tool, holding it by the crankshaft starting jaw, tightening the jaw nut only finger tight. As the cover screws are being tightened and the gasket is being compressed, tighten the jaw nut, maintaining a slight tension between the centering tool and the seal. Then remove the tool, install the starting jaw and tighten it to a minimum of 108 lbs. ft. torque.

TIMING CHAIN

1955 V8

After removing the chain case cover as outlined previously, remove the camshaft sprocket hub nut, fuel pump eccentric and dowel assembly. The camshaft sprocket and timing chain may now be taken off.

To install, rotate the crankshaft until the zero mark on the crankshaft sprocket is exactly in line with the center of the camshaft. Temporarily install the camshaft sprocket (less chain) and line up the hub dowel pin hole with the sprocket dowel pin hole, while at the same time positioning the camshaft sprocket zero mark exactly in line with the center of the crankshaft. A straight edge should be used to check the accuracy of this alignment, Fig. 28.

Remove the camshaft sprocket again and position it in the timing chain. Then place the chain on the crankshaft sprocket. Install the camshaft sprocket, being sure both zero timing marks are facing each other and in line with the center of both the camshaft and crankshaft.

Fig. 30 For correct valve timing, marks on sprockets should lineup as shown. If there is more than 3/4" slack in the chain, it should be replaced. 1955-59 Six

Fig. 31 One method of holding up valves and tappets for camshaft removal. 1955-59 Six

1956-62 V8

To install chain and sprockets, lay both the camshaft and crankshaft sprockets on the bench. Position the sprockets so that the timing marks are next to each other. Place the chain on both sprockets, then push the gears apart as far as the chain will permit. Use a straightedge to form a line through the exact centers of both gears. The timing marks must be on this line, Fig. 28.

This is the same procedure as in previous models, except that now the alignment is done on the bench rather than on the engine.

Slide the chain with both sprockets on the camshaft and crankshaft at the same time; then recheck the alignment.

1960-62 Six

1. After removing chain case cover as outlined above, take off camshaft sprocket attaching bolt.
2. Remove chain with camshaft sprocket.
3. Clean all parts and dry with compressed air.
4. Inspect chain for broken or damaged links. Inspect sprockets for cracks and chipped, worn or damaged teeth.

Installation

1. Turn crankshaft so sprocket timing mark is toward and directly in line with centerline of camshaft.
2. Temporarily install camshaft sprocket. Rotate camshaft to position sprocket timing mark toward and directly in line with centerline of crankshaft; then remove camshaft sprocket.
3. Place chain on crankshaft sprocket and position camshaft sprocket in chain so sprocket can be installed with timing marks aligned without moving camshaft, Fig. 29.
4. Install parts removed in reverse order of removal.

1955-59 Six

For correct valve timing, the timing chain and sprockets should be assembled

so that the marks on the sprockets line up as shown in Fig. 30. Follow the general procedure outlined for V8 engines.

CAMSHAFT

1955-59 Six

The general procedure for removing the camshaft is outlined below. In addition, on some earlier models it may be necessary to take off the front end sheet metal in order to provide space to extract the camshaft from the engine. This can be determined by measuring the length of the engine and comparing it with the space available between the chain case and front grille.

1. Remove radiator, cylinder head, fuel pump, oil pump and valve cover plates.
2. Support front of engine and remove front support, chain case cover, chain and camshaft sprocket.
3. Raise valves and hold them up by inserting two wooden wedges under each valve head, Fig. 31. (This operation is not necessary if valves are to be ground as the valves will have to be removed anyway).
4. Raise valve lifters and hold them up with wire, spring type clothes pins, Fig. 31, or other suitable means.
5. Rotate the camshaft as it is being withdrawn from the engine so that the cam lobes will clear successive obstacles.

1960-62 Six

Camshaft bearings in the aluminum engine are an integral part of the block and are not replaceable.

In the cast iron engine, the camshaft is supported by four precision type, steel-backed, babbitt-lined bearings. Rearward thrust is taken by the rear face of the sprocket hub, contacting the front of the engine block.

Fig. 33 Correct assembly of pistons and rods. V8s

Fig. 32 Camshaft and sprocket. Slant Six

The camshaft, Fig. 32, can be removed after removing the grille, radiator and timing chain. To remove the camshaft bearings the torque converter or flywheel must also be removed.

1. Remove valve lifters, oil pump and distributor.
2. Slide camshaft out of engine.
3. Remove welch plug back of rear camshaft bearing.
4. Remove bearings with suitable puller equipment.
5. Install new bearings, being sure the oil holes in bearings line up with corresponding oil holes in crankcase.

V8 Engines

To remove the camshaft, remove all valve lifters, timing chain and sprockets. Remove distributor and oil pump-distributor drive gear. Remove fuel pump and see that push rod has moved away from eccentric drive cam. Withdraw the camshaft from the engine, using care to see that the cam lobes do not damage the camshaft bearings.

If camshaft bearings are to be replaced, it is recommended that the engine be removed from the chassis and the crankshaft taken out in order that any chips or foreign material may be removed from the oil passages.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out of the cylinders, using care to prevent rod bolts from nicking crankshaft journals. Make sure rods and pistons are properly numbered so they can be reinstalled in their proper cylinders. It is advisable to install the caps on the rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

V8 Engines

When installing piston and rod assemblies in the cylinders, the compression ring gaps should be diametrically opposite one another and not in line with the oil ring gap. The oil ring expander gap should be toward the outside of the "V" of the engine. The oil ring gap should be turned toward the inside of the engine "V".

Immerse the piston head and rings in clean engine oil and, with a suitable piston ring compressor, insert the piston and rod assembly into the bore. Tap the piston down into the bore, using the handle of a hammer.

Assemble the pistons to the rods as shown in Fig. 33.

1960-62 Six

Piston and rod assemblies must be installed with the notch on the piston head toward the front of the engine, and the oil hole in the connecting rod toward the manifold side of the engine.

1955-59 Six

When assembling the piston to the connecting rod, assemble aluminum pistons so that the slotted side is opposite the oil hole in the connecting rod.

Install the piston and rod assembly in the cylinder so that the oil hole in the connecting rod is toward the valve side of the engine.

PISTONS

Due to the necessity of maintaining piston balance, all pistons are machined to the same weight in grams, regardless of oversize. Only finished pistons are available in service and are supplied in standard and the following oversizes: .010, .020, .030, .040, .050, .060 inch.

The recommended clearance between the thrust face of the piston and cylinder wall is .00075″ to .00175″ when meas-

Fig. 34 Checking bearing clearance by measuring width of flattened Plastigauge

ured with a micrometer and a dial indicator. Or the clearance can be checked with a ½″ wide feeler .0015″ thick.

Starting with the No. 1 cylinder, coat the bore very lightly with a light engine oil (10W). Insert the piston in the bore upside down with the feeler stock between the thrust face of the piston and cylinder wall.

While holding the piston, draw the feeler stock out straight with a spring scale attached to it. The amount of pull to withdraw the feeler stock should be as given in the chart. Fit the remaining pistons in like manner.

Service Note

The block of the aluminum engine is die-cast aluminum with cast-in-place iron cylinder bore liners .100″ thick. The liners are not replaceable. When conditions require reboring, the cylinder can be rebored up to a maximum of .040″ oversize. After reboring, do not re-chamfer the liner top so that the sealing surface at the top of the liner is maintained.

PISTON PINS

1960-62 Six

Piston pins should be a very light thumb press fit in the piston with the parts at room temperature (70°). Piston pins are supplied in standard size only. If excessive clearance is noted, both piston and pin should be replaced.

1958-62 V8-350, 361, 383

With new pistons and new pins at room temperature (70°), the pin should be a very light thumb press fit in the piston. The pin is tightly (pressed) fitted in the connecting rod. Replacement is necessary after any noticeable free play has developed between the pin and piston. Pins are available through Chrysler only with new pistons. New pistons are supplied with properly fitted pins.

1955-57 V8 & 1958-62 V8-318, 326

Piston pins are supplied in standard size and oversizes of .003″ and .008″. The fit of the pin in both the connecting rod and piston should be a tight thumb press fit with the parts at normal room temperature.

When using an expansion reamer to fit piston pins, start off by taking a very light cut. Try the fit. Then ream and try the fit again until the pin can be pushed into the rod and piston as described above.

1955-59 Six

To remove a piston pin, take off the lock rings and heat the piston in a container of hot water. Push the pin out with hand pressure. If it cannot be removed with hand pressure, use a suitable drift to drive it out.

When removing the pin with a drift, hold the piston in one hand, insert the drift and tap lightly with a hammer. Do not hold the connecting rod during this operation, otherwise misalignment of the rod may occur.

If the new pin cannot be installed in the piston with thumb pressure, enlarge the holes with an expansion reamer. Take only a light cut with the reamer. Ream the holes until the pin can be pushed into the piston with the pressure of both thumbs.

The fit of the pin in the connecting rod should be a tight thumb press fit with the parts at normal room temperature of 70°F.

PISTON RINGS

When new rings are to be installed without reboring cylinders, the glazed cylinder wall should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. The latter operation must be measured with the ring about two inches from the bottom of the cylinder bore to which it is fitted. An inverted piston can be used to push the rings down to this position. Cylinder bores and piston grooves must be clean, dry and free from carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If the feeler gauge is inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance may result.

Fig. 35 Using special tool (1) in crankshaft oil hole to turn upper main bearing in place

Fig. 37 Screws (1) must be removed from chain case cover before front bearing cap can be taken off. 1955-59 Six

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

See the *Piston and Ring Data* chart for ring groove clearances and end gap clearances.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the piston and rod assemblies merely by taking off the rod cap and replacing the upper and lower bearing halves.

The clearance between the bearings and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the bearing, Fig. 34.
3. Reinstall the bearing cap and tighten the bolts to the torque value given in the *Engine Tightening* table.
4. Remove the bearing cap again and check the bearing clearance by measuring the width of the flattened Plastigage, Fig. 34. The measuring strip is supplied in the same envelope which contains the Plastigage.

MAIN BEARINGS

V8 & Slant Six Engines

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by

tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.*

To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole, to contact the bearing and force it out, Fig. 35.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening* table.

Service Note

Servicing of main bearings in aluminum engines is identical to cast iron engines. However, make certain that any new bearings installed are applicable to the aluminum engine. The oil hole location in the aluminum upper main bearing differs from the cast iron engine location. Upper main bearings with two oil holes will fit in both engines, but upper main bearings with one hole fit only in the cast iron block.

1955-59 Six

Main bearings can be replaced after removal of the oil pan. Both standard and undersize bearings are available for service replacement (see Fig. 36).

Never use a new bearing half with an old bearing half. Never file or shim original bearing caps in an attempt to fit bearings.

To install a new set of bearings, proceed as follows:

1. Remove oil pan, clutch housing pan and oil suction pipe.
2. Disconnect chain case cover from the oil pan seal and remove oil pan gasket seal plate, Fig. 37.
3. Loosen bearing caps slightly.
4. Remove one cap at a time and replace both upper and lower bearing shells.
5. Before installing bearings, be sure crankshaft is not nicked or scored.
6. Measure clearance between bearing and crankshaft when installing either old or new bearings.
7. Plastigage may be used to measure clearance as shown in Fig. 34. Lacking Plastigage, however, coat a piece of .0015″ brass shim stock (½″ wide and 1″ long) with oil and place it between the bearing and crankshaft.
8. Install the bearing cap and draw it up tight.
9. If the clearance is not excessive, there will be a slight drag when the crankshaft is turned. The desired clearance is given in the *Engine Bearing Data* chart.
10. Tighten caps to the recommended torque.

Fig. 36 Method of identifying main bearing caps. 1955-59 Six

NOTE—The tool shown in Fig. 35 or a flattened cotter pin head may be used in the crankshaft oil hole to contact the upper bearing half and force it out.

Replacement Caps—In case of warpage or other damage to main bearing caps, replacement caps are available which have stud holes $\frac{1}{64}$″ larger than the original caps and $\frac{1}{16}$″ shorter. This permits shimming or filing to adjust for variations between original and replacement caps. Never file, dress down or shim original bearing caps.

CRANKSHAFT REAR OIL SEAL

1955-59 Six

The rear main bearing cap contains oil seals and gaskets to prevent leakage of oil at this point. The seals and gaskets should be carefully located in the cap before installation, Fig. 38.

Fig. 38 Crankshaft rear oil seals. 1955-59 six

The seal retainer bolts should be left loose until the bearing cap is tightened in order to properly locate the seal to the crankshaft.

When replacing the upper half of the two-piece seal, it will be necessary to remove the transmission and clutch and fluid drive.

V8 & Slant Six Engines

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

Fig. 39 Location of oil pan gaskets. Slant Six

OIL PAN

1962 V8-318 Engine

In order to remove the oil pan on this engine, it is necessary to disconnect the steering center link from the steering arm and idler arm. It is also necessary to turn the crankshaft front counterweight to a position providing greatest clearance for the removal of the pan.

1960-62 V8-361, 383

1. Disconnect battery cable.
2. Disconnect steering linkage from idler arm and steering arm.
3. Remove outlet vent pipe and disconnect exhaust pipe branches from manifolds.
4. Remove clamp attaching exhaust pipe to extension and remove exhaust pipe.
5. Drain engine oil and remove converter dust shield.
6. Remove oil pan bolts and lower pan, turning it counterclockwise to clear oil pick up assembly.

1960-62 Six

1. Remove tie rod at steering and idler arms.
2. Remove front engine mounting bolts.
3. Remove left side support, connecting converter housing and cylinder block.
4. Raise engine about 2".
5. Drain oil.
6. Remove oil pan bolts and lower pan down and to the rear. *Do not turn oil pick up out of position.* Install pan in the reverse order placing gaskets as shown in Fig. 39.

Service Note, 1960-62 Six

The oil pan screws must be torqued to 200 inch lbs in the sequence shown in Fig. 40. This procedure is required to minimize the possibility of oil pan gasket leakage.

In addition to the possible effect of sealing, improper torquing may cause misalignment of the clutch housing or converter housing due to crankcase distortion.

1959-61 V8-318, 326

1. Remove dipstick and drain oil.
2. Disconnect steering linkage from steering arm.
3. Remove starter.
4. On single exhaust jobs, remove exhaust crossover pipe.
5. Remove converter dust shield.
6. Raise engine about 1¼" after disconnecting front engine mounts.
7. Unfasten and remove pan, turning it sideways to clear crossmember.

1958-59 V8-350, 361, 383

1. Remove oil level dipstick.
2. Drain oil (leave plug out).
3. Disconnect steering linkage from steering arm.
4. On single exhaust system, remove crossover exhaust pipe.
5. Remove attaching screws and lower rear of pan, turning it sideways to clear crossmember.
6. Before installing the pan, clean the oil strainer and check it for alignment. The bottom of the strainer must be parallel with the lower, machined surface of the engine block.

1957 & 1958 Red Ram With Dual Exhaust

1. Drain oil and remove dipstick.
2. Disconnect steering linkage at idler arm support bracket and allow linkage to settle away from bottom of oil pan.
3. Remove starting motor.
4. Rotate crankshaft so as to bring ignition timing marks to 5 o'clock position (this will place crankshaft counterweights up in block out of the way).
5. Unfasten and drop pan as far as possible and work out over top of crossmember.

1957 & 1958 Red Ram With Single Exhaust

1. Disconnect "Y" pipe at exhaust manifolds.
2. Remove manifold heat control valve.
3. Place ignition timing marks at 5 o'clock position.

Fig. 40 Tighten oil pan screws to 200 inch pounds in the sequence shown. Slant Six engines

4. Loosen tail pipe and rear muffler support clamps.
5. Remove clamp that connects exhaust pipe to "Y" pipe.
6. Pull exhaust system rearward to break the exhaust-to-"Y" pipe connection. Work the "Y" pipe out of the way.
7. Remove starting motor.
8. Disconnect steering linkage at idler arm support bracket and allow to settle.
9. Remove engine front support attaching nuts.
10. Jack up front of engine about ½".
11. Unfasten and lower pan as far as possible and work out of position from over top of crossmember.

1955-56 V8

Disconnect steering linkage at idler arm support bracket and allow linkage to settle away from oil pan. Then unfasten and remove pan.

1955-56 Six

To remove the oil pan, remove the clutch housing lower pan to prevent damaging the oil pan gaskets on the housing. Lower the pan part way, lift up the oil strainer and take down the pan.

Fig. 41 Oil pump disassembled. V8-350, 361, 383

Fig. 42 V8 oil pump. 1955-57 and 1958 Red Ram

Before installing the oil pan, clean the pan and the pan rail of the block thoroughly and install new gaskets. Four gaskets are used as a seal between the pan and block. The gaskets are fitted into the fold-over slots of the oil pan ends to allow a more secure fit.

The right and left oil pan side gaskets may be installed with sealing compound applied on both sides. The end gaskets should be installed so that the ends of the gaskets stick out above the oil pan at least ⅛". Do not cut off the gasket ends as they will compress against the block and form a better seal as the oil pan is tightened against the block.

1957-59 Six

1. Raise car on hoist and drain engine oil.
2. Disconnect pitman arm from steering gear and idler arm from idler arm bracket.
3. Remove dust shield.
4. Remove starter motor.
5. Disconnect front engine mounts and raise front of engine approximately 2 inches. Install small block under mounts to support engine.
6. Remove pan bolts and pan.

OIL PUMP, REPLACE

1955-59 Six

Before removing the oil pump, rotate the crankshaft and make sure the "DC" mark on the crankshaft pulley lines up with the pointer on the chain case cover and that the distributor rotor is ready to fire No. 1 spark plug. After the pump is removed, do not bump the starter or let the engine turn as this will change the igniton timing.

It is necessary to remove the front engine mount "U" bolts and loosen the two rear support bolts. Then, using a suitable bar, pry the engine straight over far enough to remove the oil pump after the attaching bolts have been removed.

Use a new gasket when installing the oil pump. Line up the slots on the end of the pump shaft with the mounting holes in the pump flange. Turn the drive gear counter-clockwise one tooth and slip the oil pump into position. Check the position of the distributor rotor. It should be ready to fire No. 1 spark plug (rotor in seven o'clock position).

If the position of No. 1 piston was accidentally changed while the oil pump was removed, take out the spark plug. Rotate the crankshaft and check the compression of No. 1 cylinder. Do this by holding the thumb tightly over the spark plug hole. When the compression is felt by the thumb, turn the crankshaft until the piston is at top dead center, as indicated when the pointer lines up with the DC mark on the crankshaft pulley.

Turn the pump drive shaft until the slot in its end lines up the cap screws holes in the mounting flange. Then turn the drive gear one tooth counter-clockwise, and carefully install the pump. Do not turn the drive gear while installing the pump.

1958-62 V8-350, 361, 383

The oil pump and filter assembly, Fig. 41, is removed from underneath the engine by removing the three short and one long attaching bolts. Clean the assembly before disassembling. The filter can usually be removed by hand. However, a strap wrench can be used to unscrew it if necessary.

1955-57 & 1958-62 V8-318, 326

After removing the oil pan as outlined previously, unfasten the pump mounting bolts and drop the pump straight down and away from the engine.

When installing the pump, be sure to align the drive slot in the pump shaft with the distributor drive shaft. Install new seal rings and tighten the bolts with a torque wrench to 35 lbs. ft.

1960-62 Six

Remove oil pump attaching bolts and remove pump and filter assembly from side of engine. When installing the pump tighten the attaching bolts to 200 inch lbs.

OIL PUMP REPAIRS

1955-59 Six & 1955-62 V8

After removing the pump from the engine it should be disassembled, cleaned and inspected for wear, Figs. 41, 42, 43.

Fig. 43 Layout of oil pump parts. 1955-59 Six

Fig. 44 Oil pump and filter disassembled. 1960-62 Six

1. Remove the cotter pin holding the oil strainer to the oil suction pipe. Then remove the pipe from the pump body.
2. Remove the pump cover and discard the oil seal ring.
3. Remove pump rotor and shaft and lift out rotor body.
4. Remove oil pressure relief valve plug and lift out the spring and plunger.
5. Wash all parts in cleaning solvent and inspect carefully for damage or wear.
6. The mating face of the oil pump cover should be smooth. If it is scratched or grooved, the cover should be replaced with a new one.
7. Check for excessive cover-to-rotor wear by laying a straight edge across the cover surface. If a .0015" feeler gauge can be inserted between cover and straight edge, the cover should be discarded and a new one installed.
8. Slide rotor body and rotor into pump body and then place a straight edge across the face of the pump body between the bolt holes. If a feeler gauge of less than .003" or more than .006" can be inserted between the rotors and straight edge, install a new pump body.
9. Remove the pump rotor and shaft, leaving rotor body in pump cavity. Press rotor body to one side with the fingers and measure the clearance between rotor and pump bodies. If it is more than .012", install a new pump body.
10. Check the clearance between the pump rotor and rotor body. If the measurement is more than .012",

Fig. 46 Water pump disassembled. 1960-62 Six

install a new pump rotor and rotor body.

11. Check the oil pump relief valve plunger for scoring and free operation in its bore. If the plunger is scored, install a new one.

1960-62 Six

Refer to Fig. 44 and remove the pump cover seal ring. Press off the drive gear, supporting the gear to keep load off aluminum body. Remove rotor and shaft and lift out outer pump rotor. Remove oil pressure relief valve plug and lift out spring and plunger.

Inspection

1. The rotor contact area and the bores of the shaft and valve in the pump body should be smooth, free from scratches, scoring or excessive wear.
2. The pump cover should be smooth, flat and free from scoring or ridges. Lay a straightedge across the cover. If a .0015″ feeler gauge can be inserted under the straightedge, the cover should be replaced.
3. All surfaces of the outer rotor should be smooth and uniform, free from ridges, scratches or uneven wear. Discard a rotor less than .649″ thick and/or less than 2.469″ in diameter.
4. The inner rotor and shaft assembly should be smooth, free from scoring and uneven wear. Discard rotors less than .649″ thick.
5. Place outer rotor in pump body and measure clearance between rotor and body. Discard pump body if clearance is more than .012″.
6. Install inner rotor and shaft in pump body. Shaft should turn freely but without side play. If clearance between rotor teeth is more than .010″, replace both rotors.
7. Measure rotor end clearance. If feeler gauge of more than .004″ can be inserted between straightedge and rotors, install a new pump body.
8. The oil pressure relief valve should be smooth, free from scratches or scoring, and should be a free fit in its bore.
9. Relief valve springs are painted either gray, red or brown to denote free lengths of $2\frac{3}{16}$, $2\frac{19}{64}$ and $2\frac{25}{64}$ inches. Rather than change the length, replace a spring with one of the same color.

Fig. 45 Water pump disassembled. V8-350, 361, 383

OIL PRESSURE REGULATOR

1955-59 Six

Oil pressure is controlled by a relief valve located on the left side of the engine.

Inspect the relief valve plunger and spring after removing the valve cap and gasket. If the plunger is scratched, remove the scratches by polishing, or install a new plunger. If the old plunger is to be reinstalled, clean it and flush out the bore with engine oil by cranking the engine with the starter.

If the spring is to be replaced, use a new one of the same type. Do not use a heavier spring or a steel ball or washers behind the spring to raise the oil pres-

Fig. 47 Water pump assembly details. 1957-62 V8

Fig. 48 Layout of 1955-56 V8 water pump parts

sure. If oil pressure is low, check the fit of crankshaft bearings or look for other causes of possible loss of oil pressure.

Different colored springs are used in the relief valve. The medium spring is unpainted; the light spring is red, and the heavy spring is green. If it is necessary to replace a spring, install a spring of the same color.

RADIATOR, REPLACE

To remove radiator, drain cooling system and disconnect hoses. Remove fan shroud (if equipped). Unfasten radiator from its support and lift it out.

WATER PUMP, REPLACE

1958-62

Drain cooling system and then remove fan shroud (if equipped). Loosen fan belt and remove fan, spacer and pulley. Remove the water pump to housing retaining bolts and remove the pump.

1955-57 V8

Remove the fan and belt and disconnect water pump hose. Unfasten the water pump from the engine and lift it off.

1955-57 Six

Remove the fan and belt and disconnect water pump hose. Unfasten the water pump from the engine and lift out the pump assembly.

When installing the pump, make sure all mating surfaces are clean, and use new gaskets.

Fig. 49 Servicing 1955-56 six cylinder water pump

WATER PUMP REPAIRS

1960-62 Six

With the exception of the seal and impeller, this pump, Fig. 46, is serviced only as an assembly. When replacing the impeller or seal, install hub to obtain a dimension of .41″ between end of shaft and face of hub.

1957-59 Six & 1957-62 V8

To disassemble this type pump, use a suitable puller to pull the fan hub from the shaft. Remove the impeller by breaking the plastic away from the metal insert. Remove impeller insert and press the shaft and bearing assembly out of the housing from the impeller end, Fig. 45. *Shaft and bearing assembly need not be removed to service a leaking water pump.*

When assembled, the impeller should be flush with the end of the shaft. And when installing the fan pulley hub, press it on until there is .330″ between the end of the shaft and the front face of the hub, Fig. 47. On 1957-59 Six, install hub flush with end of shaft.

Fig. 50 Using hooked rod (2) to pull out water distributor tube. 1955-59 Six

1955-56 V8

1. Drive out fan hub retaining pin and pull off hub, Fig. 48.
2. Remove impeller and shaft.
3. Drive front bushing retaining pin through bushing and into shaft bore. Then drop out pin.
4. Use a suitable puller to remove rear bushing, thrust washer and front bushing.
5. Remove snap ring holding retainer washer and seal in impeller cavity. Slide retainer washer and seal off shaft.

Assembly—When installing the rear bushing, press it into the bore .130-.155″ beyond seat surface. Press in front bushing far enough to seat the shoulder. Install a suitable flat washer so as not to damage the bearing surface as the bushing is pressed into position.

Drill a hole in the front bushing (No. 13 drill) and install the retaining pin. Drive the pin flush with the pump body surface.

The bushings should be burnished if a burnisher is available. If not, line ream the rear bushing .6704-.6714″ and the front bushing .595-.596″. When using the reamer, be careful not to engage the thrust washer between the bushings as damage to the washer and bushings may result. Use a suitable tool to reface the seal seat.

When inserting the shaft and impeller, be certain that the flats on the shaft interlock with the lugs on the thrust washer.

When installed, the clearance between the pulley hub and front bushing should be .0005-.005″. Measure with feeler gauge.

Drill a hole through the fan pulley hub and shaft (No. 22 drill) and insert a new pin.

Lubricate the pump with water pump grease and install on the engine, using a new gasket. Torque tighten attaching bolts 25-30 lbs. ft.

1955-56 Six

Drive pin out of fan pulley hub and use a puller to pull hub off the shaft. Remove cover and pull impeller and shaft

Fig. 51 Ignition details. Distributor at rear of engine

Fig. 52 Ignition details. V8-350, 361, 383

out of body. If either impeller or shaft is to be replaced, drive out the pin holding these parts together. Drive the front bushing pin into the shaft hole of the bushing to permit removal of the bushings. Pull the bushings from the body, pulling them out toward the front. Remove the seal, spring and retainer washers from the shaft, Fig. 49.

If new bushings are to be installed, insert the thrust washer in the body with flat side facing out. Press the front bushing in with the oil groove on top and grooved end out. Press in the rear bushing, allowing $\frac{3}{32}$ inch clearance between the rear end of the bushing and the impeller housing. Drill and pin the front bushing. Remove any burrs inside the bushings and line burnish both bushings and reface the seal seat. Then continue to assemble the pump as follows:

Install the impeller on the shaft and drill for a ⅛ inch impeller pin. Install the pin and peen over both ends. Assemble the seal thrust spring, seal retainer, seal and seat retainer washer with glazed surface against seal. Install the seal retainer lock ring.

Insert the shaft and press on the fan pulley hub, leaving .003 inch clearance between the bushing and hub. Drill the shaft (if a new one is being used) and install the retaining pin. If the old shaft is being used, position the hub on the shaft so that the shaft can be drilled 90 degrees from the old hole. Remove all traces of old gaskets and install new ones. Lubricate the pump and install on the engine.

WATER DISTRIBUTOR TUBE

1955-59 Six

The water distributor tube, located in the water jacket on the valve side of the engine, should be replaced whenever the engine is completely overhauled. If the tube becomes rusted or corroded, overheating of the engine may occur due to failure of the water to circulate properly through the cylinder block.

To replace the tube, remove the radiator and water pump. Pull the tube out of the cylinder block with a stiff hooked rod, Fig. 50.

Install the new tube with the slots up and be sure it is inserted far enough into the block so that the water pump will seat properly against the block.

DISTRIBUTOR, REPLACE

To remove the distributor, disconnect the vacuum control line and low tension wire and remove the cap and lock plate hold-down screw.

When installing the distributor, make sure that No. 1 piston is on top dead center on compression stroke and that the distributor rotor is in No. 1 firing position.

IGNITION TIMING

With the distributor properly installed on the engine as outlined below, set the ignition timing with a timing light so that with the engine idling, the timing light will flash when the pointer on the engine is opposite the timing mark on the vibration damper. Chalk-mark the spot on the vibration damper so that it stands out when the light flashes (see Figs. 51 and 52).

STARTER, REPLACE

Disconnect wires and cables from starter. Then unfasten starter from flywheel housing and pull out the starter.

Service Note

Noisy or erratic starter operation may be caused by lack of lubrication or deposits of foreign material on the Bendix driveshaft.

To correct this condition, remove the inspection plate at the bottom of the torque converter or clutch housing. Then apply a suitable upper-cylinder rust inhibitor or SAE 5W or SAE 10W oil to the shaft by means of a 7" piece of tubing attached to the spout of a pressure oil can. In extreme cases, it may be necessary to remove, disassemble and clean the starter.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Adjusting Idle Speed On 1961-62 Sixes

If a condition of stalling or rough idle is encountered on cars with automatic transmission, adjust the hot idle speed to 500 rpm in Drive *with the headlights on.* It is important to make this adjustment with the headlights on so the alternator will be under full load condition. There is a variation up to 65 engine rpm between "light" and "full" charge conditions of the alternator.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

CARTER NOTES

METERING RODS

WCFB—This adjustment must be made after pump setting. Seat throttle valves in bores of carburetor and loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts vacumeter link. Hold in place and tighten clamp screw.

OVERDRIVE KICKDOWN SWITCH

BBD and BBS—With throttle valves wide open, there should be $\frac{1}{64}''$ to $\frac{3}{64}''$ clearance between kick-down lever and switch stem guide. Adjust by loosening lock nuts and adjust switch as required.

Fig. ①—BBD and BBS float level. Adjust by bending lip on float arm.

Fig. ②—Measure from top of bowl cover to top of plunger shaft with throttle connector rod in center hole of throttle lever and inner hole of pump arm. Adjust by bending throttle connector rod.

CARTER NOTES
continued

Fig. ③—With choke valve closed, tighten fast idle adjusting screw on high step of fast idle cam until the clearance between throttle valve and carburetor bore is as specified.

Fig. ④—With throttle valves wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader arm on throttle lever.

Fig. ⑤—With choke valve fully closed and fast idle cam in fast idle position, there should be the clearance specified between throttle valve and carburetor bore. Adjust by bending choke connector rod.

Fig. ⑥—With throttle valve wide open, there should be the clearance specified between upper edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

Fig. ⑦—WCFB float level. Adjust by bending float lever.

Fig. ⑧—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑨—With pump connector link in outer hole of pump arm, flat on pump arm should be parallel with a straightedge across dust cover boss. Adjust by bending throttle connector rod.

⑩—With engine at normal operating temperature, turn fast idle screw against high step on fast idle cam or on index mark until specified rpm is obtained.

⑪—With engine at normal operating temperature and choke trip lever on high step of cam.

⑫—Same as ② except connector rod goes in upper hole in pump arm.

⑬—See ⑱. Smooth floats 3/8", ribbed floats $\frac{9}{32}$".

⑭—See ⑱. Smooth floats $\frac{5}{16}$", ribbed floats $\frac{7}{32}$".

⑮—Maximum dashpot action is obtained by loosening locknut and turning dashpot unit in or out so that its plunger shaft can be moved the dimension specified with throttle valve tightly closed.

⑯—See service note "Engine Surge At Idle".

⑰—See ⑱. Smooth floats 1/4", ribbed floats $\frac{7}{32}$".

Fig. ⑱—AFB float level. Adjust by bending float lever.

Fig. ⑲—AFB float drop. Adjust by bending stop tabs on float bracket.

CARTER NOTES
continued

Fig. ⑳—Measure from top of bowl cover to top of plunger shaft with throttle connector rod in center hole of pump arm. Adjust by bending throttle connector rod.

Fig. ㉑—With throttle valves wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader lip on throttle lever.

㉒—See Note ⑩. Std. trans. 1800, auto. trans. 1600.

㉓—Pump travel is automatically taken care of when bowl vent is properly adjusted. To adjust bowl vent, open choke valve and close throttle valves. With pump rod in medium stroke hole and bowl vent clip in center notch on pump stem, a drill of the size listed should just fit between bowl vent and air horn. Adjust by bending pump operating rod.

HOLLEY CARBURETOR ADJUSTMENTS

HOLLEY NOTES

Fig. ①—Invert fuel bowl. Then loosen lock screw enough to allow adjusting nut to rotate. Turn adjusting nut until base of float is parallel with floor of bowl. Adjust both floats in same manner.

Fig. ②—With engine idling, turn adjusting nut as required until fuel just dribbles out of sight plug hole. Adjust both floats in same manner.

HOLLEY NOTES

Fig. ③—With fast idle screw in contact with high step of cam, adjust screw to open primary throttle plates the dimension listed (side toward center of carburetor).

Fig. ④—Seat screw lightly and back it off one full turn. Final adjustment is made with engine running at normal operating temperature.

Fig. ⑤—This adjustment eliminates idle instability due to icing. Turn the screw in until it seats lightly, then back it off one full turn.

Fig. ⑥—This adjustment is important in high temperature operation. With throttle closed, center of valve should clear bowl by the dimension specified. Adjust by changing the arc in rod near contact with throttle lever.

Fig. ⑦—With both throttles held wide open and pump held down, clearance between nut and pump lever should be as specified.

Fig. ⑧—Hold choke plate closed and throttle wide open. Correct clearance from choke plate to back of main body should be as specified. Adjust by bending unloader lever.

Fig. ⑪—Check actual fuel level through economizer opening with a 6" scale and depth gauge as shown. Level listed is taken between outer surface of carburetor body and level of fuel.

Fig. ⑨—With transmission in neutral, engine temperature normalized and fast idle screw on second step of cam, turn adjusting screw in or out to obtain 1300 rpm on manual and 1400 rpm on automatic transmission cars.

Fig. ⑩—With carburetor inverted, install float gauge. Check setting on "touch" side of gauge. Reverse gauge and check setting on "no touch" side. Adjust float level by bending tab on float lever.

HOLLEY CARBURETOR NOTES
continued

Fig.⑫—With throttle closed, bowl vent should be adjusted so that the shank of a drill of the size listed can be inserted between valve and surface of carburetor body. Bowl vent operating lever can be bent up or down to provide proper clearance.

⑬—With choke and throttle plates closed, index mark on fast idle cam, Fig. ①, should line up with center of fast idle adjusting screw. To adjust, bend fast idle link as required.

Fig. ⑭—The automatic choke includes a vacuum piston in the carburetor and a remote thermostat mounted on the manifold heat well. Remove welch plug with a sharp punch to remove choke piston and link for cleaning. Install and set new plug with brass drift.

STROMBERG NOTES

CARBURETOR BALL CHECKS

Whenever it becomes necessary to dismantle a carburetor be sure to account for the ball check valves that may be found under pump plungers and compensating or power valves.

Fig. ①—WW float level. Adjust by bending float lever.

STROMBERG NOTES continued

Fig. ②—With choke valve held open, pump travel from fully closed to fully open position should be as specified. Adjust by bending pump rod.

③—With throttle valves closed, turn fast idle screw out until it rests on high step of fast idle cam. Then turn screw in the number of turns specified.

Fig. ④—With throttle valves wide open, choke valve should open the dimension specified between edge of choke valve and wall of air horn. Adjust by bending tang on throttle lever.

⑤—With engine running at normal operating temperature, turn fast idle screw against highest step on fast idle cam until specified rpm is obtained.

Fig. ⑥—WW float level. Invert main body so weight of floats only is forcing needle against its seat. There should be the distance listed from surface of fuel bowl to crown of float at center.

Fig. ⑧—This setting is made after pump travel setting. With throttle fully closed and choke valve wide open, test opening of bowl vent valve at center of hole with rubber valve hanging free. If opening is not as specified, bend bowl vent lever as required.

⑨—Pump travel is automatically taken care of when bowl vent valve is properly adjusted.

⑩—With throttle valves tightly closed it should be possible to insert a drill of the size listed between bowl vent and vent seat protruding through air horn. Adjust by bending pump rod as required.

Fig. ⑦—With throttle valves wide open, choke valve should open the dimension specified between edge of choke valve and wall of air horn. Adjust by bending ear on throttle lever.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1960-62

The procedure for adjusting the clutch is the same as that outlined for 1957-59 with the following exception. When adjusting the overcenter spring the adjusting nut should be turned up five turns on 10, 10½ and 11″ clutches and three turns tighter than finger tight for 9¼″ clutch.

1957-59

To compensate for normal clutch wear, adjust the clutch release fork rod to obtain $\frac{5}{32}$″ free play of clutch release fork outer end. This will provide a one-inch free pedal movement at the pedal with a total of six-inch pedal travel.

When necessary to adjust the over-center spring, back off the over-center spring adjusting nut until it is free of the "C" link. With the clutch pedal depressed to the full six-inch travel, turn the adjusting nut until the nut just contacts the "C" link. Then tighten seven full turns for the 10″ clutch or five full turns for the 9¼″ clutch—*no more*—from the finger-tight position.

1955-56

Adjust the clutch fork rod in or out as required to secure $\frac{3}{16}$″ free play of the clutch release fork outer end. This will provide the one inch free pedal movement at the pedal pad with a total of 7″ full pedal travel, Fig. 1.

The upper end of the clutch pedal pivots in the lower end of the mounting bracket on needle bearings in the V8 and nylon bushings in the Six. These bearings require no periodic lubrication. However, they should be lubricated with wheel bearing grease if the pedal is removed for any reason.

CLUTCH SERVICE

Unless special clutch rebuilding equip-

Fig. 1 Clutch pedal and linkage. 1955-56

ment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If clutch rebuilding equipment is available, follow the equipment manufacturer's instructions, Fig. 2.

Removal

1. Remove transmission and clutch pan.
2. Pull out clutch release bearing and sleeve.
3. Mark clutch cover and flywheel so they may be assembled in the same relative position and thus maintain original balance.
4. Remove capscrews which retain clutch cover to flywheel. Loosen each screw a few turns in succession until cover is free.
5. Clutch assembly and driven disc may now be removed from the clutch housing.

Installation

1. Coat the pilot bearing in crankshaft with wheel bearing grease.
2. Clean surfaces of flywheel and pressure plate, making certain no oil or grease remains on these parts.
3. Hold cover plate and disc in place and insert a special clutch aligning tool or a spare clutch shaft through the hub of the disc and into the crankshaft pilot bearing.
4. Bolt clutch cover loosely to flywheel, being sure marks previously made are lined up.
5. To avoid distortion of clutch cover, tighten cover bolts a few turns each in progression until all are tight. The final tightening should be 15-20 lb. ft. torque.
6. Install transmission by guiding it into place with guide studs inserted in the two top holes of the clutch housing.
7. Adjust clutch pedal free travel.

TRANSMISSION, REPLACE

1. Disconnect propeller shaft at front. (On cars with overdrive, remove solenoid and disconnect control cable).
2. On all cars, disconnect speedometer cable, hand brake cable, and gearshift rods from transmission.
3. Remove two upper transmission mounting studs and insert guide pins in their place.
4. Remove other mounting studs and slide the transmission back and out. On 1958-62, it is necessary to support engine and remove crossmember.

When installing, use the guide studs and handle the transmission carefully to avoid damage to the clutch disc.

TRANSMISSION REPAIRS

1955-59 Plymouth
1955-62 Dodge V8

(For detailed service on overdrive transmission, see the *Overdrive* chapter. To disassemble the standard transmission, see Fig. 3 and proceed as follows:

1. Remove speedometer drive pinion.
2. Take off cover and gear selector, roll transmission over and remove balls.
3. Use a puller to remove mainshaft flange and brake drum.
4. Remove shifter fork guide rail.
5. With gears in neutral, remove shift fork lock screws.
6. Remove plug for lower shift rail.
7. Slide shift rails out through front of case.
8. Lift out shift forks.
9. Remove extension housing and mainshaft, being careful not to allow synchronizer to become disassembled.
10. Strip mainshaft of synchronizer, second speed gear and sliding gear.
11. Release snap ring and pull mainshaft out of extension housing.
12. Remove mainshaft bearing, spacer and speedometer drive gear.
13. Pull bearing and oil seal from extension housing.
14. Drive countershaft through rear of case, allowing cluster gear to lie in case.
15. Remove main drive gear and bearing, and disassemble parts.
16. Lift out cluster gear and related parts.
17. Drive reverse idler shaft out rearward and lift out gear.

Fig. 2 Clutch. 1955-59

Assembly Notes—Use new gaskets, oil seals and snap rings, being sure snap rings fit snugly in their grooves.

When assembling cluster gear, place steel washer plates next to gear and bronze washers next to case. Select the proper thickness bronze washers to provide end play of from .002 to .008 inch.

If a special oil seal drift is not available, be sure that oil seal protrudes $\frac{7}{32}$ inch out of the mainshaft extension housing.

Referring to Figs. 4 and 5 for synchronizer assembly, place one bent up end of synchronizer spring into pocket of shifting plate. Then install bent up end of other spring into pocket of same plate on opposite side of synchronizer. Spring on one side should leave plate in opposite direction from spring on other side.

Assemble the synchronizer unit on the mainshaft as shown in Fig. 6.

If second speed gear end play is not within .003 and .008 inch, use a snap ring of different thickness.

Install first and reverse shifter rail on top, other rail on bottom, Fig. 7.

Install gearshift housing as shown in Fig. 8.

1960-62 Six

1. Referring to Fig. 9, remove transmission flange.
2. Remove extension housing.
3. Remove transmission cover.
4. Remove clutch shaft bearing retainer.
5. Grasp clutch shaft with hand and pull assembly out of case. *Be careful not to bind inner synchronizer ring on clutch teeth.*
6. With transmission in reverse, remove outer center bearing snap ring, using a hook or a flat blade, then partially remove mainshaft.
7. Cock mainshaft; then remove synchronizer sleeve, rings and 2-3 shift fork.
8. Remove clutch gear snap ring, using snap ring pliers. Slide clutch gear off end of mainshaft.
9. Slide second speed gear, stop ring and synchronizer spring off mainshaft.
10. Remove low-reverse sliding gear and shift fork as mainshaft is withdrawn from case.
11. Using a feeler gauge, check end play of cluster gear, which should be .004" to .012". This measurement

Fig. 3 Manual shift transmission. 1955-59 Plymouth and 1955-62 Dodge V8

will determine if new thrust washers are to be installed at reassembly.

12. Drive countershaft rearward and out of case. Remove key from end of shaft.

Fig. 4 Shifting plates (2) fit in stop ring slots (1). Standard transmission

13. Lift cluster gear and thrust washers out of case. Disassemble cluster gear by removing needle bearings (22 each end) and spacer.
14. Using a suitable drift, drive reverse idler gear shaft towards rear and out of case. Remove key from shaft.
15. Lift out reverse idler gear, thrust washers and needle bearings (22) out of case. Remove needle bearings from gear.

Assembly Notes

Reassembling the transmission is accomplished by reversing the disassembly procedure. However, observe the following:

1. When installing the reverse idler gear, have the bevelled ends of the gear teeth forward. Raise the idler gear slightly to align with shaft; then drive shaft into case, through thrust washer and gear, until end of shaft is approximately $\frac{1}{64}$" below surface of case.
2. Cluster gear thrust washers are available in two sizes marked "A" and "B". Make a selection to give .004" to .012" total end play of cluster gear. Make sure tabs on thrust

Fig. 5 Installing synchronizer shifting plates and spreader spring.

Fig. 9 Manual shift transmission. Dodge 1960-62 Six and all 1960-62 Plymouth. A Plymouth Heavy Duty model for 1960 is similar except that it has a removable side cover. The Plymouth 1961 heavy duty model is also similar, the chief difference being the cut of the mainshaft splines. Also the offset side of the hub of the low-reverse gear goes toward the rear

washers slide into grooves in case. Countershaft should be installed until approximately $\frac{1}{64}$" below surface of case.

3. When installing mainshaft, have offset of low-reverse fork to rear. Engage fork in low-reverse gear, then position in case by shifting into reverse.
4. After sliding the synchronizer clutch gear on mainshaft and down against second speed gear, select a snap ring of the correct thickness and install. *Snap ring should eliminate end play and must be a snug fit.*
5. Check clearance between clutch gear and second speed gear, which should be .003" to .008". *End play in excess of .008" will permit gear "jump out."*
6. After mainshaft is properly positioned, select a snap ring that will be a snug fit at the rear bearing.

Fig. 6 Mainshaft and extension housing assembly

GEARSHIFT, ADJUST

1955-56

To adjust the control rod, loosen the lock bolt at the upper lever on the lower end of the steering column. Set the transmission gears in neutral and the hand control lever in the horizontal position and tighten the lock bolt.

To adjust the shift control rod, set the transmission gears in neutral and loosen the lock nut on the selector rod at the transmission end. Tighten the nut until all play is eliminated and back off ½ turn for clearance and tighten.

1957-58, 1960-62 Manual Trans.

This transmission incorporates an individual rod shifting mechanism, Fig. 10, which simplifies maintenance, improves shift quality and decreases shifting effort.

Cross-over adjustments and gearshift operating lever positions are adjusted by threads on the upper ends of the shift

Fig. 7 Shifter rails

Fig. 8 Installing gearshift housing

Fig. 10 Manual transmission shift linkage. 1957-58, 1960-62

rods. Movement of the shift lever should be smooth when moving through the cross-over position.

If an up and down motion at the hand lever is experienced during cross-over, the shift rod length should be adjusted by turning the adjusting nuts on one rod to vary the trunnion position on the rod. This will raise or lower the lever at the lower end of the steering column and thus align the cross-over. The hand lever knob must be in a horizontal position following cross-over adjustments.

If the lever binds when moving into a gear position after cross-over, check the position of the gearshift tube support at the lower end of the steering column. The support should be moved up to relieve binding on the second-to-high side and down for the low-to-reverse side.

Cross-Over Adjustments

Before making the cross-over adjustment, Fig. 11, the gearshift lever shaft must be in its normal fully returned position in neutral. Then proceed as follows:

1. Remove grease fitting from tube lever pin retainer. Rotate retainer until gearshift tube cross pin is exposed.
2. If a .040″ round feeler cannot be inserted between pin and bottom of slot as shown in Fig. 11, an adjustment at the gearshift tube lower support must be made as follows:
3. Loosen lower support screws slightly. Move support by tapping lightly with a plastic hammer. On cars with power steering, do not attempt to separate lower support after loosening.
4. Adjust support up or down as required to secure the necessary .040″ clearance.
5. Tighten support clamping screws to 150 *inch* lb. torque (90 *inch* lb. for power steering equipped cars).
6. Rotate tube-lever pin retainer to original position and install grease fitting securely. (Loss of fitting will result in loss of cross pin).

Control Rod Adjustments

After completing foregoing adjustments, be sure gearshift lever travels freely and equally up and down in either high or second gear position and low or reverse positions. Check the cross-over adjustments, Fig. 12, with the manual lever by making the cross-over from second-to-direct and from low-to-reverse. Cross-over must be free of interference. Transmission must be in neutral when making the following adjustments:

1. Loosen adjusting nuts at second-to-direct control rod swivel.
2. Turn both adjusting nuts in direction required to locate hand lever in horizontal plane.
3. Tighten adjusting nuts securely to swivel block.
4. Loosen adjusting nuts at low-to-reverse gearshift control rod swivel.
5. Position low-to-reverse gearshift lever in direct alignment (through center of swivel lock pin) with second-to-direct gearshift lever. Tighten adjusting nuts securely to swivel block.

Caution: Failure to make this adjustment correctly will result in insufficient manual lever-to-steering column clearance or manual lever-to-operator's leg clearance. Damage to the transmission is also possible because of incomplete engagement of gears.

1959 Manual Trans.

Check position of steering column jacket. Gearshift and turn signal levers must have adequate clearance under steering wheel. If necessary, loosen jacket clamps, position jacket and tighten clamps. Check gearshift tube for interference or drag at instrument panel bracket, the floor pad and the tube support lower bracket. Eliminate any looseness of control rods in operating levers at transmission. Levers must be in neutral when making the following adjustments:

1. Lever travel (free play) up and down (toward or away from steering wheel) in first or reverse should equal the lever travel in second and high. Adjust by loosening the lower bracket clamp and moving the bracket up or down. Tighten clamp to 40 inch-pounds.
2. Outer (knob) section of control lever should be horizontal with transmission in neutral and lever at rest (away from steering wheel). Adjust length of rod attached to tube lower lever (2-3 shift).
3. Shifting through crossover should be smooth. Adjust length of rod attached to tube upper lever (1-R shift) to attain smooth crossover; then shorten rod an additional two turns to insure disengagement from low when fast shift is made.

Fig. 11 Checking gearshift lever shaft in Neutral position. 1957-58, 1960-62

Fig. 12 Gearshift control rod adjustments. 1957-58, 1960-62

POWERFLITE

A detailed service procedure on this transmission is given in the *Automatic Transmission Section* of this manual.

Transmission, Replace

1. Drain transmission and converter.
2. Disconnect front universal and secure propeller shaft to frame.
3. Remove hand brake linkage.
4. Disconnect speedometer cable, neutral starter and back-up light wires from switches.
5. Disconnect throttle linkage from lever at transmission.
6. Remove push button control cable (if equipped).
7. Remove oil cooler lines (if equipped).
8. Remove nuts from rear engine mount and support engine with a suitable jack.
9. Remove crossmember, leaving engine rear support adapter attached to transmission.
10. Unfasten transmission from converter housing and slide it straight back and out of car.
11. Reverse foregoing procedure to install.

POWERFLITE THROTTLE LINKAGE

Dodge 1955-58 V8

1. Be sure there is no bind in the throttle linkage; if there is, correct this condition before proceeding.
2. Run engine until normal operating temperature is reached.
3. Remove air cleaner to make definitely sure choke valve is fully opened.
4. Connect tachometer leads to coil and ground.
5. Adjust engine idle speed to 475-500 rpm with transmission in neutral.
6. Loosen throttle linkage adjusting screw (located on accelerator shaft-to-carburetor rod.

7. Move rear portion of this rod rearward until it is stopped by the idle stop on the transmission throttle cam.
8. With rods in line and rear portion of rod pre-loaded, lock throttle linkage adjusting screw securely.

Dodge 1955-58 Six

The operations outlined for the V8 engines apply to 6-cylinder models except Steps 6, 7 and 8, which are as follows:

1. Loosen throttle linkage adjusting screw, located on throttle control rod from engine to carburetor.
2. While holding throttle control rod against closed throttle stop, move bellcrank arm just enough to start extending the accelerator return spring. *Do not extend spring more than ⅛″ in opposite direction.*
3. With control rods in line and preloaded slightly, lock throttle rod adjusting screw securely.

Plymouth 1955-58 V8

The throttle linkage adjustment is made on the throttle control rod. Loosen the clamp nut on the throttle control rod and slide the rear part of the rod toward the rear of the car to take up all slack. Then tighten the clamp nut. *Be sure carburetor is "off" the fast idle when making the adjustment.*

Plymouth 1955-58 Six

Loosen the vertical clamp rod and adjust the carburetor lever rod to provide 5 7/16″ distance between the anchor points of the throttle return spring. Then with engine idling (off fast idle) take up the slack at the vertical rod and tighten the clamp nut.

1959 V8

1. With engine shut off and carburetor off fast idle, disconnect transmission throttle rod at carburetor.
2. With rod held to limit of travel rearward, the distance from the dash to the bellcrank should be ½″ to 9/16″. If correct, the balance of the linkage is properly adjusted and all that is necessary is to adjust the throttle rod length to fit between bellcrank (held to rear) and carburetor lever. If dimension is correct, proceed as follows:
3. Connect throttle rod to carburetor.
4. With engine running at operating temperature and carburetor off fast idle, adjust idle speed to 475-500 rpm with transmission in neutral.
5. Loosen adjusting lock nuts on transmission throttle rod and the rod at transmission.
6. Adjust throttle rod to correct length by holding bellcrank ½″ to 9/16″ from dash while tightening lock nut on rod.
7. Accelerator pedal should be 115 deg. from horizontal, measured from rear of pedal. If necessary, adjust accelerator rod under slanting toe-board.
8. Adjust length of rod at transmission by holding transmission lever forward against internal stop while tightening lock nut on rod.

1959 Six

1. With carburetor choke valve fully open and throttle off fast idle, the distance from heater housing to center of bellcrank ball stud should be approximately 2¼″. Length of linkage spring should be 8¼″.

Fig. 15 Removing Powerflite push button control cable from transmission (oil pan removed to show operation)

2. Only when heater housing to ball stud distance is correct can the throttle rod be adjusted to produce 8¼″ spring length. If heater housing to ball stud distance is incorrect, proceed as follows:
3. With engine at operating temperature and carburetor off fast idle, adjust idle speed to 475-500 rpm with transmission in neutral.
4. Loosen lock nuts on throttle rod above cylinder head and the rod at the transmission.
5. While holding heater housing-to-bellcrank ball stud distance at 2¼″, adjust throttle rod to produce the 8¼″ spring length.
6. Adjust accelerator pedal-to-bellcrank rod to hold the pedal 115 deg. from the horizontal.
7. Adjust length of rod at transmission by holding transmission lever forward against internal stop while tightening lock nut on rod.

Dodge 1960-61, Plymouth 1960 All & 1961 Six

1. With engine at operating temperature, carburetor off fast idle cam and transmission in neutral, adjust idle speed to 475-500 rpm.
2. Loosen throttle adjusting lock nuts on both carburetor rod and the transmission throttle rod.
3. Insert a 3/16″ rod in the hole and open slot of accelerator shaft bracket end into the elongated hole of the throttle lever.
4. With rod in position, hold transmis-

Fig. 13 Throttle linkage. Dodge and Plymouth 1960-61 V8

Fig. 14 Powerflite push button controls (typical)

sion throttle valve lever all the way forward and tighten transmission to accelerator lever assembly rod adjusting lock nut "A", Fig. 13.

5. Remove rod from accelerator lever, shaft and bracket assembly.
6. With carburetor throttle lever off fast idle cam and against the idle stop screw, move the rear half of the carburetor rod rearward until the stop in the transmission is felt, tighten lock nut "B", Fig. 13.
7. The accelerator pedal should be at an angle of 114° to the horizontal. If necessary to adjust, remove accelerator pedal end of the bell crank to pedal rod, and shorten or lengthen the rod by loosening lock nut at the swivel end and rotate the swivel. Reinstall the rod and tighten the lock nut. *Be sure the rod is properly aligned to prevent binding. Poor engine performance due to carburetor throttle not opening fully or lack of kickdown may result if pedal angle is incorrect.*

Plymouth 1961 V8

1. With lock nuts loose in carburetor and transmission rods, insert a $\frac{3}{16}$" rod approximately 10" long into the holes provided in the accelerator shaft bracket and lever.
2. Move transmission throttle lever forward against stop and tighten transmission rod lock nut.
3. Disconnect one end of accelerator pedal rod and adjust its length to provide a pedal angle of 113° to 115°.
4. Remove $\frac{3}{16}$" rod.
5. Open choke valve and open throttle slightly to release fast idle cam, then return throttle to hot idle position.
6. Move rear of carburetor rod rearward until stop is contacted and tighten carburetor rod lock nut.

POWERFLITE PUSH BUTTONS

1955-61

Mechanical connection between push button unit, Fig. 14, and the manual control valve is obtained through the use of a single push-pull cable. One end of the wire cable is secured to the cable actuator in the speed range selector unit on the instrument panel. The other end enters the transmission case to engage the manual control valve assembly.

Fig. 16 Powerflite control cable backlash adjustment

Fig. 18 Torqueflite gearshift control unit (typical)

Cable Remove, Push Button End

Remove bezel attaching screws, then remove bezel and push buttons. Remove nuts holding push buttons unit to instrument panel and remove push button unit from rear of panel. The cable bracket is held by two screws to the push button unit. A hairpin clip secures the cable to the actuator bar.

Cable Remove, Trans. End

Remove throttle adjusting hole plug and allow transmission fluid to drain off to the level of the hole. Remove neutral starter switch to provide access to the cable lock spring. Remove cable bracket. On star wheel type, push "R" button in to place cable adapter near switch hole. Insert screwdriver through neutral switch hole. Push gently on projecting portion of cable lock spring and pull outward on cable, Fig. 15.

Cable Install, Trans. End

Push in "L" button. Place transmission manual valve lever in reverse detent by moving neutral switch contact part of lever full travel towards rear of car manually, by using a screwdriver in neutral switch hole. With "L" button held tightly in, insert cable into transmission case engaging cable ferrule groove with lock spring in cable adapter. Push and pull the cable, using pressure, to be sure groove in ferrule has engaged lock spring. Replace mounting bracket and tighten cap screw finger tight.

Cable Adjustment

Loosen and move cable bracket assembly manually at the transmission as required, to position manual valve lever into neutral. Hold "N" button tightly in at full travel. The neutral starting switch cam should then be practically centered in its mounting hole. Use a free fitting flat nosed rod, inserted throught the neutral switch mounting hole, and then apply light pressure against the manual valve lever to maintain the neutral detent position of the manual lever. Carefully move cable assembly in and out, without moving the manual lever, to determine total free-play travel of cable. Locate the cable in mid-position of the free-play, Fig. 16,

Fig. 17 Wheel type push button cable adjustment. 1959-62 Torqueflite

release the pressure against the manual lever and tighten the mounting bracket securely. *Do not allow the cable to move when tightening the bracket or backlash setting will be disturbed.* Replace neutral switch and check fluid level.

V8 TORQUEFLITE

Transmission, Replace

1. Disconnect battery.
2. Place push button in "1" position ("R" position on 1960-61) so as to be able to remove cable from adapter housing on transmission.
3. Drain transmission and converter.
4. Disconnect front universal joint.
5. Disconnect hand brake linkage.
6. Disconnect speedometer cable.
7. Disconnect neutral starter switch wire.
8. Disconnect throttle control linkage at transmission.
9. Loosen push button control cable adjustable mounting bracket or adjustment wheel locking screw.
10. Remove control cable adapter housing plug, insert screwdriver through hole, release cable spring lock and remove cable from adapter housing.
11. Using same screwdriver, insert through cable opening in housing and push lever rearward to last detent. Then reinstall housing plug and tighten.
12. Remove oil cooler lines from transmission (if equipped).
13. Unfasten rear engine support from crossmember.
14. Remove starting motor.
15. Support engine with suitable jack.
16. Raise engine slightly and remove crossmember.
17. Unfasten and remove transmission from converter.
18. Reverse foregoing procedure to install transmission.

TORQUEFLITE SIX

Transmission, Replace

1. Disconnect battery.
2. Depress "L" push button to position control cable for removal from transmission.
3. Remove starting motor.
4. Drain transmission and converter.
5. Disconnect neutral switch wire and remove switch.
6. Remove control cable to transmission adjusting screw, insert screwdriver through neutral switch opening and push gently against upper projecting portion of cable lock spring and pull outward on cable to remove cable from adapter and case.
7. Loosen clamp screw and remove throttle link and lever assembly from throttle shaft.
8. Disconnect oil cooler lines at transmission and remove filler tube.
9. Remove speedometer pinion and sleeve from transmission and disconnect front universal joint.
10. Remove parking brake cable from brake support.
11. Remove nuts securing transmission extension housing insulator to the crossmember.
12. Support engine with suitable jack.
13. Raise engine slightly and remove crossmember.
14 Place transmission jack under transmission.
15. Mark converter and flex plate to assure correct assembly. Remove converter to flex plate mounting screws and attach a small "C" clamp to edge of bell housing to hold converter in place during transmission removal.
16. Remove bell housing bolts and carefully work transmission rearward off engine block dowels and to disengage converter hub from end of crankshaft.
17. Lower transmission jack and remove transmission and converter.
18. Reverse foregoing procedure to install transmission.

TORQUEFLITE PUSH BUTTONS

Wheel-Type Cable, 1959-60

1. To remove the cable, drain approximately three quarts of oil from the transmission.
2. Engage "1" push button.
3. Remove adjusting wheel lock screw, Fig. 17.
4. Remove neutral starter switch, cupped washer and seal.
5. With a screwdriver inserted through neutral starter switch opening, push gently against the upward projecting portion of the control cable adapter lock spring and pull outward on cable to remove cable assembly from case.

Fig. 19 Torqueflite manual control cable adjustment (non-wheel type)

Fig. 20 Throttle linkage adjustment. 1958 Torqueflite

Install and Adjust

1. Engage "R" push button. *Have an assistant hold this button firmly until the transmission end of the cable has been adjusted and locked.*
2. Back off the cable adjustment wheel (turn counter-clockwise) on cable housing until only two or three threads are showing. *Caution: do not back the wheel entirely off the guide threads because it serves as a stop prevent the "O" ring from going too far into the case and becoming caught inside the case when the cable is installed.*
3. Push cable control housing into the transmission case with just enough force to overcome the "O" ring friction and to bottom the assembly. While holding the cable firmly into the bottomed position, rotate adjusting wheel clockwise *to just contact the transmission case.*
4. Release the inward pressure on the cable and then turn the adjusting wheel until the next adjustment hole in the wheel lines up with the lock screw hole in the case. Counting this hole as number one, continue turning the wheel clockwise until the fifth hole lines up with the screw hole in the case. Check cable adjustment to be sure of full detent in all shift ranges.
5. Install neutral starter switch and refill transmission with oil.

Non-Wheel Type Cable, 1959

1. Raise vehicle on hoist and drain 2 quarts of fluid from transmission.
2. Engage "L" push button.
3. Remove control cable lock clip.
4. Remove plug and locking screw.
5. With screwdriver inserted through plug hole, push gently against upward projecting portion of control cable adapter spring and pull outward on cable to remove cable from adapter housing.
6. Insert screwdriver into cable entrance hole in cable adapter housing and push cable adapter to limit of travel to the reverse detent position. Remove screwdriver.
7. Reinstall plug and locking screw in adapter housing.

8. Turn locking screw with screwdriver counter-clockwise until locking screw contacts adapter. Tighten locking screw firmly against adapter to cause adapter to bind against adapter housing. *Do not over-tighten screw as adapter housing may be damaged.*
9. Engage "R" button.
10. Hold cable in alignment with hole in adapter housing.
11. Push cable into housing until adapter spring engages groove in cable end.
12. With a helper firmly holding the "R" button in at full travel position, carefully position cable housing at midpoint of cable backlash, Fig. 19.
13. While continuing to hold "R" button firmly, tighten cable adjusting clip screw securely, being careful not to move cable during tightening process.
14. With screwdriver, turn adapter locking screw clockwise to limit of travel. Tighten 10 to 16 inch lbs. In this position, locking screw seats against inner end of plug and prevents oil leakage at this point.

Cable Adjust, 1957-58

1. "R" push button must be depressed and held all the way in during adjustment.
2. Loosen cable lock clip screw at transmission.
3. Push cable in until it stops; then release cable.
4. Tighten cable clip screw, making sure cable housing is not forced in or out during adjustment.
5. To check for proper operation, push the various buttons, return to "N" each time while checking starter operation. Engine should start only when "N" button is depressed.

Fig. 21 Throttle linkage. 1960-61 Ram Manifold engine

TORQUEFLITE THROTTLE LINKAGE

Dodge 1957 Four Bar. Carb.

1. With engine at operating temperature and idle speed adjusted to 475-500 rpm, loosen throttle linkage adjusting nut on rod from bell crank to intermediate throttle control.
2. Hold light pre-load rearward on rod so that throttle valve lever is against the stop in the transmission.
3. Tighten throttle adjusting nut.
4. Adjust accelerator pedal rod by removing rod at pedal arm. Loosen lock nut and turn ball and socket end of rod in direction required so that pedal can be depressed just down to floor mat without compressing mat.

Dodge 1957 Two Bar. Carb.

All operations are the same as four barrel carburetor except that, since there is no intermediate throttle control, adjustment is made on the bell crank to carburetor rod.

Dodge 1958-59 Four Bar. Carb.

1. With engine at operating temperature and idle speed set at 475-500 rpm, loosen throttle linkage adjusting nuts on carburetor-to-bell crank rod, and on bell crank-to-transmission rod.
2. Adjust carburetor-to-bell crank rod to position the lever ½" from cowl dash panel (see "A", Fig. 20) and tighten adjusting nut.
3. Dimension "B" should be 8½". Hold slight pre-load rearward on bell crank-to-transmission rod while holding transmission throttle valve lever forward against the stop, and tighten adjusting nut.
4. The accelerator pedal should be at an angle of 115 degrees to the horizontal (see "C", Fig. 20). If necessary to correct, remove the rod and rotate the swivel as required. Reinstall rod and tighten lock nut.

Dodge 1958-59 Two Bar. Carb.

All operations are the same as the four barrel carburetor except that since there is no intermediate throttle control assembly, the adjustment is made on the bell crank-to-carburetor rod.

Plymouth 1957-59 4 Bar. Carb.

1. With engine at operating temperature and idle speed adjusted to 475-500 rpm with transmission in neutral, loosen throttle linkage adjusting nut on bell crank-to-intermediate throttle control.
2. Hold light pre-load rearward on rod so that throttle valve lever is against stop in transmission.
3. Tighten throttle adjusting nut.
4. Adjust accelerator pedal rod by moving pedal-to-accelerator shaft rod at pedal arm. Loosen lock nut and turn ball and socket end of rod in the direction required to adjust the pedal so that wide open throttle is obtained when the pedal is depressed just down to the floor mat but not compressing it.

Plymouth 1957-59 2 Bar. Carb.

All operations are the same as the four barrel carburetor except that since there is no intermediate throttle control assembly, adjustment is made on the bell crank-to-carburetor rod.

1960-61 Six

1. With engine at operating temperature and carburetor off fast idle cam, adjust idle speed to 500 rpm.
2. Loosen lock nut and move transmission throttle control lever forward until it stops. Tighten lock nut.
3. Check accelerator pedal angle. It should be 115°. To adjust, disconnect pedal and adjust rod length. When correct, reconnect pedal.

Fig. 22 Throttle linkage. 1962 Dodge and Plymouth Six

Fig. 23 Tool used to adjust cable housing ferrule in clamp. 1962 all models

Fig. 24 Throttle linkage. 1962 V8-318 engine

Fig. 25 Throttle linkage. 1962 V8-361 engine

1960-61 V8

The procedure is the same as that outlined previously for the 1960 Powerflite.

1960-61 Ram Manifold

Refer to Fig. 21 and perform the following operations to properly adjust the linkage:

1. Loosen adjusting nuts "A" and "B".
2. Insert a $\frac{3}{16}$" drill rod, 10" long into the accelerator shaft bracket and through the hole in the lever.
3. Move transmission throttle control lever forward until it stops and tighten locknut "A" securely. This positions accelerator shaft.
4. Unsnap accelerator pedal to shaft rod.
5. Turn threaded end of rod in or out to obtain 114° angle between floor of car and flat face of accelerator pedal and connect rod.
6. Remove drill rod from accelerator shaft bracket.
7. Inspect carburetors to be sure that choke valves are open, fast idle cams are released and throttle valves are closed.
8. Loosen locknuts "C" and "D" and back off anti-stall plunger far enough to allow bellcrank to be pivoted.
9. Pivot bellcrank until a $\frac{3}{16}$" drill rod, 3" long can be inserted through bellcrank hole and down into intake manifold.
10. Tighten locknuts "C" and "D" and remove the drill rod from the bellcrank.
11. Push rearward on the accelerating shaft to throttle shaft lever rod adjusting link until stop is reached and tighten locknut "B" securely.

1962 With Manual Trans.

1. Referring to Figs. 22 to 25, disconnect choke at accelerator or block choke valve in full open position.
2. Open throttle slightly to release fast idle cam, then close throttle.
3. With cable clamp nut loose, insert a $\frac{3}{16}''$ diameter rod approximately 4 inches long in the holes provided in the dash bellcrank and lever assembly. This locates the bellcrank and pedal at the correct angles until the final adjustment is completed.
4. Adjust position of cable housing ferrule in the clamp, using the tool shown in Fig. 23 so that all slack is removed from cable with carburetor at slow idle position. To remove slack from cable, move ferrule in clamp in the direction away from carburetor lever. Tighten clamp nut.
5. Remove $\frac{3}{16}''$ rod. Connect or unblock choke.

1962 With Auto. Trans.

1. Referring to Figs. 22 to 25, remove transmission rod ball socket from ball end.
2. Disconnect choke at carburetor or block choke valve in full open position.
3. Open throttle slightly to release fast idle cam, then close throttle.
4. Hold transmission lever forward against its stop and adjust length of transmission rod by means of the threaded adjustment at the upper end. The correct length has been attained when the ball socket lines up directly with the ball end. *The ball socket must be at the same height as the ball end when checking rod length.*
5. Assemble ball socket to ball end. If the transmission rod adjustment is correct, the transmission lever will be in its extreme forward position with the carburetor at slow idle. When the carburetor throttle is opened, the transmission lever will begin its travel at the same time with no vertical movement of the lever or vertical movement of the rod in the lever.
6. Loosen throttle cable clamp nut and insert a $\frac{3}{16}''$ diameter rod approximately 4 inches long in the holes provided in the dash bellcrank and lever assembly.
7. Adjust position of cable housing ferrule in the clamp, using the tool shown in Fig. 23 so that all slack is removed from cable with the carburetor at slow idle. To remove slack from cable, move the ferrule in the clamp in the direction away from the carburetor lever. Tighten clamp nut.
8. Remove the $\frac{3}{16}''$ rod. Connect or unblock choke.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

The drive pinion is held in position by the shoulders in the differential carrier upon which the pinion bearing cups seat. The pinion position is maintained by a washer or shims located between the pinion head and the rear bearing cone. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings, Figs. 1 and 2.

Axle Shaft & Oil Seal

To remove the outer oil seal on these models, take off the wheel, hub and drum. Then disconnect the brake tube at the wheel cylinder, and remove the brake support. Drive out the old seal and remove the burrs from the support plate to prevent damaging the new seal.

With the brake support removed, install the new seal from the outer side of the brake support plate. Then stake the plate in three places with a center punch to hold the seal in position. Install the special tool, Fig. 3, in the seal or use other suitable means to protect the leather portion of the seal from being damaged by the axle shaft keyway and install the brake support as shown. Remove the tool and complete the installation of the brake support, hub and drum and wheel.

To remove the axle shaft and inner oil seal, disconnect the brake line and remove the wheel hub and drum assembly. *Do not use a knock-out type puller or strike the ends of the axle shafts to loosen wheel hubs as this may damage the bearings.* Remove the axle shaft keys and install the special sleeve shown in Fig. 3 to protect the seal while removing brake supports, seals and bearing shims. Keep each set of shims separate to assure proper assembly. Use a suitable puller to remove the axle shaft and bearing from the housing. Then pull the inner oil seal from the housing.

Axle Shaft End Play, 1955-61

To adjust axle shaft end play, add or remove shims to obtain the desired end play of .003 - .008". When adjusting bearings, remove or install an equal thickness of shims on the right and left sides of the axle housing to maintain central position of shaft thrust block.

Fig. 1 Rear Axle

Axle Shaft End Play, 1962 Six

Due to limited clearance at the axle shaft thrust block in this new axle makes necessary a new procedure for adjusting rear axle shaft end play.

1. With axle assembled and axle shaft bearing cups in place (brake backing plates removed) push both axle shafts in toward the center of the housing as far as they will go.
2. Starting with the right side, determine that the right axle shaft and cup are pushed in as far as they will go.
3. Measure the amount the left axle shaft bearing cup extends out beyond the end of the axle housing.
4. If the distance is less than .040″, no shims are needed on the left side.
5. If the distance is greater than .040″, subtract .040″ from the distance measured and install shims equal in total thickness to the remaining amount.
6. For example: Distance measured is .050″, subtract .040″. Shim pack on that side should be .010″.
7. Install brake backing plate on left side.
8. Push right axle shaft and bearing cup in as far as they will go, and measure the distance the bearing cup extends out of the housing.
9. Add .018″ to the measurement obtained and add shims totaling this amount to that side.
10. For example, bearing cup extends out .020″. Add .018″ to this amount. Total shim thickness used should be .038″.
11. Install right backing plate.
12. Measure axle shaft end play after assembly is complete.
13. End play should be .013 to .023″. If not within these limits, change shims as necessary *on the side assembled last.*

Fig. 2 Rear axle

Rear Axle Repairs

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

Pinion & Bearings, Replace

The differential unit must be removed before the drive pinion can be taken out, but it is not necessary to remove the drive pinion or differential unit if only the drive pinion bearing oil seal is to be replaced.

To remove the oil seal, take off the pinion flange retaining nut and use a suitable tool to remove the flange. The oil seal may then be pulled out of the carrier.

Pull the drive pinion through the gear end of the differential carrier. The bearing spacer, front bearing and shims may then be taken out. Using a bearing puller, remove the rear bearing cone from the pinion shaft and, unless the ring gear and pinion are to be replaced with new parts, use care not to allow the front and rear shim packs to become mixed.

If the differential unit was satisfactory from the standpoint of noise before the unit was dismantled, the drive pinion may be assembled with the original shims (or washer) behind the rear bearing. If new parts are used, or if an adjustment was necessary, change the shims until the correct combination is obtained to locate the pinion properly.

To assemble, place the front bearing in position in its cup and install the pinion shaft oil seal. Place the washer or shims on the pinion shaft against the pinion head and press on the rear bearing. Slip the bearing spacer against the rear bearing, then place the front bearing shims ahead of the spacer. Install the pinion and assembled parts in the carrier, passing the forward end of the pinion through the front bearing. Replace the pinion flange, slip on the washer, screw on the retaining nut and tighten securely.

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearings are tight, but still permit rotating the pinion by hand.

The bearings should be pre-loaded

Cross and roller universal joint

.0015 to .0025 inch. To check and adjust this pre-load (tension) mount a dial indicator on the carrier with the stem of the indicator contacting the pinion flange. Then if the indicator, for example shows .004 inch end play, remove the parts including .006 inch of shimming to give the necessary .002 inch draw tension or pre-load on the bearings.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion should be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle* chapter. If a correction is necessary, disassemble the parts and, if the pinion is to be moved toward the center of the axle, add shims or install a thicker washer (whichever is used) between the pinion head and the rear bearing cone. If the pinion has to be moved away from the center of the axle, remove shims or install a thinner washer.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle* chapter. When the adjustment is correct, install a new cotter pin in the pinion retaining nut.

Ball and trunnion universal joint

BRAKE MASTER CYLINDER, REPLACE

1955-59

To remove the master cylinder, remove pedal return spring. Disconnect push rod by removing shoulder bolt and nut. Disconnect brake line tube at master cylinder, and stop light switch wires. Unfasten cylinder from its mounting and remove from dash panel.

Fig. 3 Installing axle shaft outer oil seal with special sleeve

POWER BRAKE UNIT

1962

1. With the engine not running, pump the brake pedal about six times to destroy the vacuum stored in the booster.
2. Disconnect booster push rod from brake pedal lever by removing one nut and shoulder bolt.
3. Disconnect hydraulic brake line from master cylinder.
4. Disconnect vacuum line from vacuum check valve at top of front shell of booster housing.
5. Disconnect booster from firewall reinforcement plate by removing four stud nuts from passenger compartment side of firewall.
6. Remove booster and master cylinder as an assembly. A plastic gasket is used between booster and reinforcement plate. Discard this gasket; a new one is part of the repair kit.
7. Remove master cylinder from booster (4 studs).
8. *The booster assembly is serviced as a unit with the exception of the vacuum check valve and vacuum seal.*

1955-61

1. To remove the unit, insert a wooden wedge or block between the power lever and bracket (this will prevent damage to the ramp of the trigger arm).
2. Scratch alignment marks across the power unit adjacent to the vacuum test port and across the mounting bracket.
3. Disconnect vacuum hose from end of power unit.
4. Remove master cylinder push rod eye bolt from pedal.
5. Remove stop light switch wires and master cylinder brake tube from master cylinder.
6. Remove master cylinder.
7. Unfasten the power unit from the dash panel and slide the unit and bracket straight out.
8. Reverse above procedure to install the power unit, being sure to align the scribe marks made before removal.

Front End and Steering Section

CASTER & CAMBER, ADJUST

1955-62

Caster and camber adjustments are accomplished by means of the upper control arm attaching bolt and cam assemblies, Fig. 1.

On 1962 models, access holes to loosen the upper control arm cam bolt nuts are provided in the upper control arm mounting for making caster and camber adjustments.

To adjust caster and camber, carefully loosen the upper control arm adjusting bolt nuts while holding the bolts to prevent turning. Record caster and camber readings.

Adjustment of caster through camber readings is possible because of the consistent relation between caster change and camber change when either the front

Fig. 1 Upper control arm and frame brackets. 1959-62

or rear cam bolt at each control arm is individually rotated.

Turning one bolt affects caster more than camber. Turning both bolts an equal amount in the same direction affects camber directly, and caster indirectly. Turning the cams an equal amount in opposite directions will change caster with little change in camber, depending on the relative position of the cams.

By bringing caster within specifications by turning one bolt at a time, then by turning both bolts an equal amount to bring camber to the preferred reading, the caster will usually be brought close to the preferred setting.

After both caster and camber readings are correct, tighten the nuts to a torque of 65 lbs. ft. while holding the bolts from turning.

Always recheck the settings after tightening the nuts since the bolts may have turned slightly during the tightening process.

Service Note

The direction the cam is turned initially depends upon the position of the high spot of the cam. The procedure is to turn the eccentric in either direction until the desired movement takes place. If you continue turning past the high spot of the cam the movement will start to reverse. In other words, the high spot is the limit of adjustment in either direction.

1957-58

Adjustments are performed by installing $\frac{1}{16}$" and $\frac{1}{32}$" shims between the upper control arm support brackets and the frame sub-side rails. Installing or removing shims at either the front or rear bracket changes the *caster* setting. Installing or removing shims equally at both brackets changes the *camber*.

Raise the car from the floor and loosen the upper control arm support bracket bolts. Add or remove shims as required and tighten bolts. *Adding shims equally at both front and rear support brackets will decrease positive camber.* One shim $\frac{1}{16}$" thick at each bracket will change camber $\frac{5}{16}$ degree.

Addition of shims to the front bracket or removal of shims at the rear bracket will decrease positive caster. One shim $\frac{1}{16}$" thick will change caster approximately ½° (¾° on 1958). Total thickness of each shim pack should *not* exceed $\frac{9}{16}$" (⅝" on 1957).

After lowering car, jounce front end up and down a few times before rechecking wheel alignment to allow suspension to assume normal position.

1955-56

Caster is not adjustable but the proper setting is obtained when assembling the camber eccentric bushing. To adjust camber, loosen the clamp screw and turn the bushing to obtain the correct setting within a half revolution from the point where the correct caster setting is obtained. Do not turn the bushing until it binds against the upper control arm.

TOE-IN, ADJUST

1955-61

With the steering wheel in mid-position, loosen the clamps on the end of both rods and turn both ends until the wheels are straight ahead. Then, without disturbing the steering wheel, turn both tie rods an equal amount until the toe-in is correct and equal at each wheel.

1962

With the front wheels in the straight ahead position, loosen the clamps at each end of both adjusting tubes. Adjust toe-in by turning the tie rod sleeve which will "center" the steering wheel spokes. If steering wheel was centered, make the toe-in adjustment by turning both sleeves an equal amount. Position the clamps so they are on the bottom and tighten bolts to 15 ft. lb.

WHEEL BEARINGS, ADJUST

1. Tighten wheel bearing adjusting nut to 90 inch pounds torque while rotating wheel.
2. Position nut lock on nut with one pair of slots in line with cotter pin hole.
3. Back off lock and adjusting nut to next slot.
4. Install cotter pin. The resulting adjustment should be zero to .003" end play.
5. Clean grease cap, coat inside with wheel bearing grease (do not fill) and install cap.

Fig. 2 Torsion Bar Suspension

Fig. 3 Torsion bar spring cam and height adjustment. 1957-59

Fig. 4 Torsion bar rear support. 1960

Fig. 6 Sectional view of upper and lower ball joints

Fig. 5 Front suspension height adjustment. 1961-62

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first make sure the front wheel bearings are properly adjusted and that the control arms are tight.

Although Dodge publishes no specific recommendations, a reliable method is to jack up under the lower control arm near the outer end. Then grasp the tire at the top and bottom and move it in and out. If wheel movement or play in excess of ¼" is evident, replace the joint or joints as required.

TORSION BAR SUSPENSION

Service Notes

1. When necessary to install new torsion bars, remove all accumulated dirt, scale and moisture from inside torsion bar rear anchor.
2. Do not apply heat to anchor assembly in order to remove bar. Use an arbor press to remove bar from anchor whenever necessary.
3. Coat inside of anchor with multipurpose grease.
4. The torsion bars have a pre-set loading for right and left usage. Bars can be indentified by the letter "R" or "L" stamped on one end of bar. This letter is not visible when the bar is installed. However, the last three digits of the part number can be seen from the anchor end of the bar; the left bar is stamped with the odd number, the right bar with the even number.
5. Always install new torsion bar rear anchor seal.
6. In every case where a bar is being replaced for breakage, apparently as a result of corrosion within the rear anchor, it should be assumed that the other bar would be in a similar condition, and both bars should be replaced.
7. The torsion bar adjusting bolt should only be loosened (or tightened) with a foot pound torque wrench with vehicle supported under frame to relieve load on torsion bars. If more than 200 ft. lbs. is required to turn the adjusting bolt, then the bolt and swivel must be replaced.
8. If the vehicle is to be raised on a hoist, make sure it is lifted on the frame only so the front suspension is in full rebound under load.

TORSION BAR, REPLACE

1957-59

1. Raise vehicle by jacking under frame crossmember. Release load from torsion bar by unscrewing anchor adjusting bolt partly out of swivel.
2. Remove lock ring from rear of anchor. Slide torsion bar rearward enough to disengage foward end of bar from lower control arm. Then move forward to disengage bar from anchor. Remove bar, swivel and cam from frame bracket anchor.

Installation

1. Assemble anchor, swivel, bolt seat (oval side up) and bolt in frame anchor bracket. Check for torsion bar cushion in lower control arm housing. With cam bolt barely entered in cam swivel, slide bar into rear cam.
2. Rotate anchor and torsion bar until anchor is positioned as close as possible to floor pan. Engage front of bar in lower control arm shaft as far as bar will go. *Unless anchor blade is in the position just described when installing bar, it will be impossible to adjust front suspension to the proper height.*
3. Center and install lock ring in rear of anchor housing. Pressure may be applied to bar to enable lock ring to be installed.
4. After lock ring is installed, tighten cam bolt until approximately one inch of threads are showing above anchor bolt swivel. *This is an approximate setting used merely as a starting point when adjusting sus-*

pension height. This setting is also necessary to place load on torsion bar before lowering vehicle to floor.

5. Check and adjust suspension height as outlined further on.

1960-61

1. Raise vehicle by jacking under center of front crossmember.
2. Release load from torsion bar by backing off anchor adjusting bolts.
3. Remove bolt and swivel and discard.
4. Remove plastic seal from rear end of torsion bar anchor, and remove lock ring from anchor.
5. Slide torsion bar toward rear of car enough to disengage forward end from lower control arm. Slide bar forward and down, disengaging it from anchor, and remove bar.

Installation

1. Slide new anchor end seal over end of bar with cup side facing rear.
2. Install torsion bar and position seal in groove on anchor hub.
3. Turn torsion bar until anchor is positioned approximately 120° (8 o'clock position) down from frame. *If anchor end is not in this position when installing bar it will be impossible to adjust the suspension to the correct height.* Engage front of bar in hex opening in lower control arm.
4. Before installing lock ring, center bar so that full contact is obtained at anchor and control arm shaft. Install lock ring in groove.
5. Pack anchor seal with grease and position lip of seal in anchor hub groove. Install plastic seal in rear end of anchor.
6. Slide adjusting bolt swivel on frame and install adjusting bolt and seat. Tighten bolt into swivel until approximately one inch of threads are showing out of swivel. *This is an approximate setting used as a starting point when adjusting for correct suspension height. This setting is also necessary to place a load on the bar before lowering vehicle to floor.*
7. Lower car to floor and adjust suspension height as outlined below.

SUSPENSION HEIGHT, ADJUST

1. Jounce car so parts can assume normal position.
2. Measure from lower ball joint to floor and from bottom of lower control arm bushing housing to the floor.
3. Subtract one measurement from the other. The difference should be as listed below subject to a tolerance of plus or minus ⅛".

Plymouth

1957-58 Sedans and Coupes	2 3/16"
Suburbans	2 11/16"
Fury	1 11/16"
1959 Sedans and Coupes	2⅛"
Suburbans	2½"
1960-61 Sedans and Coupes	2"
Suburbans	2½"
1962 All	1½"

Dodge

1957 Sedans and Coupes	2⅛"
Suburbans	2⅝"
Sports Models	1⅝"
1958 Sedans and Coupes	2 3/16"
Suburbans	2 11/16"
Sports Models	1 11/16"
1959 Sedans and Coupes	2⅛"
Suburbans	2½"
1960-61 Sedans and Coupes	2"
Suburbans	2½"
1962	1½"

If these measurements differ more than ⅛" or if one or both of them are outside the specified limits, the suspension height of both sides must be adjusted. To adjust, turn the anchor bolt clockwise to raise the height and counterclockwise to lower it, Figs. 3, 4 and 5.

BALL JOINT SERVICE

1. To replace ball joints, Fig. 6, raise car by jacking under lower control arm and remove wheel assembly.
2. Remove upper and lower ball stud nuts and slide tool shown in Figs. 7 and 8 down over lower stud until it rests on steering knuckle.
3. Turn threaded portion of tool, locking it against ball joint being removed. Spread tool enough to place ball stud under pressure, then strike the steering knuckle sharply with a hammer to loosen the stud. *Do not attempt to force stud out of knuckle with tool alone.*
4. Remove tool, then disengage ball joint from knuckle.
5. Remove dust cover and grease seal.
6. Remove grease fitting and unscrew ball joint from control arm.
7. When installing ball joints, it is important that the threads engage those of the control arms squarely. Torque the ball joints to the control arms to 125 ft. lbs., the lower stud nut to 135 ft. lbs., and the upper stud nut to 100 ft. lbs.

FRONT END REPAIRS

1955-56

Shock Absorber

1. Raise hood and clean the area around the upper mounting, Fig. 9.
2. Slide a wrench over the flats on top of the shock absorber piston rod to keep the rod from turning. Then remove the nut and cup washer.
3. Remove the two lower mounting bolts and withdraw the shock absorber through the opening in the spring seat. Lower cup washer may remain in place or drop through when shock absorber is removed.
4. Using a suitable drift, force the inner steel sleeve out of the bushing and remove the bushing from the frame opening.
5. Before installing a new bushing, dip it in soapy water and insert in the frame with a twisting motion. When installed properly, the groove in bushing will index the frame.
6. Force steel sleeve through opening in bushing and down into position.

Fig. 7 Removing upper ball joint from steering knuckle

Kingpins & Bushings

1. Remove wheel and hub assembly.
2. Block brake pedal so it cannot be depressed.
3. Unfasten brake support plate from knuckle.
4. Remove steering arm from knuckle.
5. Remove brake hose and connection and lift off brake support.
6. Remove kingpin lock pin.
7. Drive a punch into upper steering knuckle welch plug and pry out plug.
8. Drive kingpin downward, forcing out lower welch plug. A soft brass drift should be used in driving against top of kingpin.
9. If needle bearings are used in the knuckle they should be removed with a suitable puller. A puller should also be used when pressed-in bushings are employed.

When installing needle bearings they must be installed from the top of the knuckle with the trade mark on top and the oil hole lined up with the oil hole in the steering knuckle.

Pressed-in type bushings must be line reamed.

After installing the steering knuckle, make sure it is free in the support as binding at this point may cause sensitive steering and car wander. There should be .008 in. clearance between the

Fig. 8 Removing lower ball joint from steering knuckle

knuckle and knuckle support. This clearance can be adjusted by the use of shims between the knuckle and thrust bearing.

After their installation, welch plugs should be staked in place.

Upper Control Arm

1. With a jack under the lower control arm spring seat, raise the car and remove the wheel.
2. Remove shock absorber.
3. Unscrew bolt from outer end of control arm.
4. Unfasten and remove control arm pivot bar.

Lower Control Arm

To remove the lower control arm, raise the front end of the car off the floor and place a support under the frame side member behind the suspension unit. After removing the wheel, disconnect the shock absorber and the sway eliminator at the lower shock absorber mounting stud. Place a jack under the control arm pivot bar where it is attached to the frame cross member. Use a block of wood cut to receive the lower control arm bar between the jack and the bar, which will prevent the jack from slipping. Now rease the jack just enough to relieve the pressure on the pivot bar fastening bolts. Remove the bolts, placing tapered drifts in each hole, to prevent binding of the last bolt removed. Lower the jack slowly, allowing the lower control arm to come down, then lift out the spring. Remove the lower control arm pin from the knuckle support and take out the lower control arm assembly.

Fig. 9 Front suspension, 1955-56 (typical)

HORN SOUNDER & STEERING WHEEL

Dodge 1960-61

1. Disconnect battery ground cable.
2. Remove screws from underside of steering wheel and remove stationary plate, bushings, horn ring and attaching screws.
3. Disconnect horn wire at stationary plate.
4. Loosen wheel nut three turns. Use puller to loosen wheel. Then remove puller, nut and wheel.

Dodge 1955-59

1. Disconnect battery.
2. Remove two screws on underside of medallion and remove medallion.
3. Disconnect horn wire from terminal on travel plate and insulator.
4. Remove horn ring, travel plate and insulator, contact spring plate and ground plate. Push horn wire aside to make room for steering wheel puller pilot.
5. Remove wheel nut and use puller to remove wheel.
6. To install, reverse above procedure. Be sure that master serrations on wheel and shaft are aligned and that the turn signal cancelling cam on the bottom of the wheel is inserted between switch levers.

Plymouth 1961

1. Disconnect battery ground cable.
2. Remove two screws from underside of steering wheel and remove horn ring.
3. Disconnect wire at horn switch, remove screws and lift out switch.
4. Loosen steering wheel nut several turns and install a puller to loosen wheel.
5. Remove puller, nut and wheel.

Plymouth 1957-60

1. Disconnect battery ground cable.
2. Remove screws from underside of steering wheel and remove stationary plate, bushings, horn ring and attaching screws.
3. Disconnect horn wire at stationary plate.
4. Loosen wheel nut three turns. Install puller and loosen nut.
5. Remove puller, nut and wheel.

Plymouth 1955-56

Remove steering wheel ornament and contact plate by depressing center and rotating it counterclockwise until it pops out. Remove horn ring by removing three retaining screws.

Remove wheel nut, install puller and remove wheel. If horn wire has been left in tube, push it down into end of tube to avoid damage when using puller.

MANUAL STEERING GEAR, REPLACE

1955-61

1. Remove horn button or blowing ring and steering wheel as outlined previously.
2. Remove left front wheel.

3. Remove front seat cushion and floor mat after sliding draft pad up on column.
4. Remove floor pan pedal opening cover.
5. Disconnect turn signal control wires (if equipped) at connections under instrument panel. *Time will be saved if a length of wire is attached to the loose ends of the turn signal wires before withdrawing through the jacket tube. This will enable all wires to be drawn back through the tube at reassembly.*
6. Remove transmission shifting mechanism at steering column.
7. Unfasten gear housing from frame.
8. Disconnect Pitman arm.
9. Remove steering gear post bracket cap at instrument panel.
10. On 1955-56 models, remove steering gear from bottom side of car by withdrawing as far as possible and bending to right side of car.
11. On 1957-59 models, remove steering gear by withdrawing it up through opening in floor pan.
12. On 1960-61 models, slide steering gear jacket tube rearward and remove through drivers compartment. Remove tapered retainer and spring fom the column tube. Unfasten the steering gear from the frame and slide the gear toward rear of car and at the same time raise the lower end of the gear and remove through hood opening.

MANUAL STEERING GEAR REPAIRS

1955-61

In this type steering gear, Fig. 10, the worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth roller is attached to the roller shaft by means of a steel shaft. Two needle bearing assemblies are installed between this shaft and the roller. (Some light duty models have a two tooth roller shaft).

The roller shaft is mounted in the steering gear housing on two needle bearing assemblies which are pressed into the housing. The housing cover is attached to the housing by four cap screws. An adjustment screw, mounted in the cover, controls roller shaft end play and worm and roller mesh adjustment.

The steering wheel and roller shaft arm (pitman arm) are splined to the steering shaft and roller shaft respectively. Both the pitman arm and steering wheel have master splines to insure correct installation.

Worm End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the four cover screws about ⅛".
3. Use a knife to separate the top shim, passing the blade all the way around between the shims, being careful not to damage the remaining shims.
4. Remove one shim at a time between inspections to remove the end play.

Fig. 10 Manual steering gear. 1961

5. The adjustment is correct when there is no end play and no stiffness in the steering gear throughout the complete range of its travel.

Roller Shaft End Play, Adjust

1. Turn the steering gear to either extreme and back off ⅛ of a turn.
2. Gripping the pitman arm at the hub, the roller shaft should rotate freely without a particle of end play.
3. If end play exists, adjust as required by means of the roller shaft adjusting screw in the side cover.
4. Be sure to tighten the lock nut securely and inspect for end play and free rotation throughout the entire range of steering gear travel.

Worm & Roller Mesh, Adjust

1. Loosen the roller shaft adjusting screw lock nut.
2. With the steering gear in its central position (drag link disconnected) tighten the roller shaft adjusting screw just enough to remove play between the roller shaft roller tooth and worm.
3. Check this by the amount of play felt at the pitman arm. It is better to leave a slight amount of play at this point than to tighten too much.
4. If tightened beyond the point where the lash is removed, serious results will occur which will cause poor steering operation.
5. Tighten the adjusting screw lock nut.

POWER STEERING, REPLACE

1961-62

1. Disconnect battery ground terminal.
2. Pull steering arm from steering gear.
3. Remove bolt attaching lower coupling to steering gear worm shaft.
4. Unfasten steering gear from frame (3 bolts) and slide gear assembly toward front of car to disengage column tube flexible coupling from steering worm shaft.
5. Remove gear through engine compartment.
6. When installing the gear, align the index mark on the outside of the flexible coupling hub with the master spline on the steering worm shaft.

1958-60

1. To remove the unit, disconnect battery ground cable.
2. Disconnect horn wire.
3. Remove horn button, horn ring and horn wire.
4. Remove steering wheel.
5. Disconnect turn signal wires at connectors and on 1960 models, remove turn signal switch and also remove retainer snap ring from groove in steering tube at top of bearing.
6. Remove jacket tube support brackets at instrument panel.
7. Loosen two bolts attaching jacket tube to steering housing, push jacket tube upward to expose steering coupling pin and remove pin.
8. Remove nut at drag link-to-steering arm ball joint.
9. Disconnect pressure and return hoses at steering gear. Fasten disconnected ends of hoses above oil level in reservoir. Cap hose ends and fittings on steering gear to prevent entrance of dirt.
10. Remove steering arm with puller.
11. Unfasten gear housing from frame and remove steering gear at engine compartment.
12. On cars with Ram Manifold, remove left front wheel and fender opening panel. Raise lower end of gear housing in a clockwise motion towards cowl panel until the gear shaft end of the housing and shaft will clear the "A" frame of front suspension. Then tilt gear assembly towards engine slightly to allow swinging the gear downward through opening at fender side panel.
13. Reverse foregoing procedure to install the steering gear.

1955-57

1. Remove two screws from horn ring ornament and remove ornament from steering wheel.
2. Disconnect horn wire, remove three horn ring screws and remove horn ring.
3. On 1957 models, remove front seat cushion.
4. Remove steering wheel.
5. Remove turn signal lever.
6. Remove steering column-to-instrument panel bracket and shroud.
7. Loosen steering column jacket clamp screws.
8. Raise front of car and disengage drag link from pitman arm.
9. Use suitable puller to remove pitman arm from steering gear shaft.
10. Loosen three gear housing-to-frame attaching bolts and lower front of car to floor.
11. Pull jacket from steering shaft.
12. Remove floor mat retaining plate, dust pad and access plate.
13. Place a large pan underneath unit. Then disconnect pressure and return hoses and drain gear by rotating it until all oil is expelled from unit.
14. Fasten disconnected ends of hoses above oil level in reservoir to prevent further loss of oil and cap ends to prevent any foreign matter from entering.
15. On 1955-56 models, raise front of car from floor and remove gear housing-to-frame attaching bolts and align-

ment wedge. Then remove the gear from the lower side of the car.

16. On 1957 models, remove steering gear attaching bolts. Then lift the steering gear up through the opening in the floor pan.

Speedometer, Radio & Windshield Wiper

WINDSHIELD WIPER

Plymouth 1955-59

The wiper is held in position by studs which attach the mounting brackets on the motor to the windshield belt bar reinforcement. Remove the radio to facilitate removal of wiper motor. Use care so as not to damage the linkage when removing. When installing motor be sure not to tighten the attaching studs too tightly as the rubber mounting will be distorted resulting in wiper motor noise.

Plymouth 1960-61

1. Remove glove compartment door and remove glove compartment.
2. Remove bolts attaching wiper motor bracket to cowl panel to instrument panel brace.
3. Disconnect wires at wiper motor.
4. Disconnect links at pivot cranks. Clips are removed by lifting the top tab and sliding it sideways out of engagement with the groove in the pivot crank pin.
5. Remove the spacing washer and remove link from the pivot crank.
6. Slide the wiper motor and links far enough towards the left so that right hand link will clear glove compartment opening and remove using care not to bend the links.

1962 Dodge & Plymouth

1. Remove radio, speaker grille and speaker.
2. Remove bolts attaching wiper motor bracket-to-cowl panel-to-instrument panel brace.
3. Disconnect wires at wiper motor.
4. Disconnect links at pivot cranks. Clips are removed by lifting top tab and sliding it sideways out of engagement with groove in pivot crank pin. The right pivot may be reached through glove box opening.
5. Tip wiper motor and bracket on its side and remove left link.
6. Remove right defroster tube, the pencil brace between instrument panel reinforcement and wiper motor mounting.
7. Remove motor and mounting through speaker opening.

Dodge 1955-59

The wiper motor should be operated and shut off by turning off the ignition. The motor must not be disassembled when the cranks are in the parked position or damage to the motor switch and contact follower will occur when the cover is removed. To remove the wiper, proceed as follows:

1. Disconnect wires at motor.
2. Remove radio and right-hand fresh air door.
3. Disconnect links at pivot cranks. Clips are removed by lifting the top tab and sliding it sideways out of engagement with groove in pivot crank pin.
4. Remove spacing washer and link from pivot crank.
5. Disconnect mounting bracket at dash panel and remove wiper motor and bracket.
6. Reverse procedure to install, being sure rubber mounting gasket is in place.
7. Adjust wiper parking position by moving cam adjustment lever which projects from switch cover.

Dodge 1960-61

1. Remove glove compartment door.
2. Remove glove compartment.
3. Remove bolts ataching wiper motor bracket to cowl panel to instrument panel brace.
4. Disconnect wire at wiper motor.
5. Disconnect links at pivot cranks. Clips are removed by lifting the top tab and sliding it sideways out of engagement with the groove in the pivot crank pin.
6. Remove spacing washer and remove link from pivot crank.
7. Slide wiper motor, with links, far enough towards the left so that right hand link will clear glove compartment opening in panel and remove assembly. *Use care so as not to bend the links.*

RADIO REMOVAL

Dodge 1955-56

Disconnect radio and speaker wires. Unfasten radio from its mounting and remove from instrument panel.

Dodge 1957-59

Disconnect battery ground cable and "A" terminal lead wire at temperature gauge. Disconnect radio and speaker wires. Unfasten radio from its mounting and remove from instrument panel.

Dodge 1960-61

Disconnect battery, antenna "A" lead, light lead and front and rear speaker leads. Remove ash tray assembly to gain access to mounting bolts. Remove mounting bolts and remove radio-to-dash support bracket. *Do not operate radio with speaker detached since damage to transistors may result. If rear seat speaker is disconnected from radio, insert a jumper wire in speaker socket to allow the radio to operate.*

Plymouth 1955-56

1. Disconnect antenna lead at radio and battery wire at fuse holder.
2. Disconnect dial light and speaker at radio.
3. Remove two lower grille attaching screws (inside glove box).
4. Remove four upper molding screws.
5. Remove two screws in upper part of radio panel.
6. Remove radio bracket screw inside glove box at top.
7. Pull radio out of panel.

Plymouth 1957-58

1. Disconnect antenna lead at radio and battery lead at fuse holder.
2. Disconnect pilot light and speaker at radio.
3. Remove four screws from front of radio panel.
4. Loosen radio bracket screw under radio and pull radio out of panel.

Plymouth 1959

1. Disconnect radio antenna lead-in wire at radio and disconnect battery wire at fuse holder.
2. Disconnect speaker leads.
3. Remove manual tuning knob, on-off control knob and mounting nuts.
4. Remove mounting screw located behind ash tray. Loosen attaching nut on radio mounting bracket at instrument panel. Remove radio from rear of instrument panel.

Dodge & Plymouth 1960-62

1. Disconnect battery, antenna "A" lead, light lead and speaker leads.
2. Remove control knobs and shaft mounting nuts.
3. Remove bracket-to-receiver attaching bolt.
4. Remove speaker grille from top side of instrument panel by lifting up the left corner and sliding the grille out.
5. Remove speaker mounting screws and remove speaker.
6. Remove heater push button assembly.
7. Remove radio through speaker opening of instrument panel.

SPEEDOMETER

Dodge 1955-56 & Plymouth 1955-58

1. Disconnect battery.
2. Disconnect speedometer cable housing.
3. Remove four speedometer to panel attaching screws in back of panel.
4. Remove speedometer assembly from behind the dash.

Dodge 1957-59

1. Disconnect battery.
2. Disconnect speedometer cable housing.
3. Remove four speedometer bezel retaining screws, accessible from the face of the instrument panel.
4. Move speedometer out of dash toward steering wheel.

Plymouth 1959

1. Disconnect battery.
2. Disconnect speedometer cable housing.
3. Remove two screws from the top of the instrument cluster which are accessible from the outside.
4. Remove two nuts from the bottom of the instrument cluster behind the dash panel.
5. Move instrument cluster toward steering post and disconnect all wiring.
6. Disassemble speedometer from instrument cluster.

Plymouth 1960

1. Disconnect battery ground strap.
2. Remove screws securing bezel to pod and remove pod.
3. Remove screws located at each end of lower nacelle.
4. Gently pull upper nacelle toward rear of car to release two spring-type retainers located at rear of upper nacelle. When spring retainers clear cavity in lower nacelle lift upper nacelle clear.
5. Disconnect all electrical connections.
6. Remove screws at bottom center of lower nacelle. This screw prevents "rocking" of speedometer in its supports that are integral with lower nacelle.
7. Loosen two nuts on studs located on back of speedometer housing and gently lift speedometer until sufficient clearance is obtained to release drive cable.
8. Reverse above procedure to install.

Plymouth 1961

1. Disconnect battery ground strap.
2. Remove four screws attaching speedometer and instrument panel cover to the base.
3. Remove panel cover by raising front edge slightly to clear instrument cluster and carefully pushing panel toward windshield to disengage retaining spring clips from speedometer and instrument panel base.
4. Disconnect wires and bulb sockets from instrument panel.
5. Remove four screws attaching speedometer and instrument cluster and bezel to speedometer and instrument panel base. Remove clusters and bezel as an assembly.
6. Disconnect speedometer cable and lamp connectors at speedometer head.
7. Remove speedometer from panel base.

1962 Plymouth

To service any of the instruments, including the speedometer, it is necessary to remove the instrument cluster from the panel.

1. Disconnect battery cable.
2. Remove heater blower switch knob.
3. Remove temperature control knob.
4. Disconnect speedometer cable.
5. Remove four screws visible on the face of the cluster bezel.
6. Pull cluster assembly forward and tilt it downward to expose wiring harness, connectors and printed circuit.
7. Disconnect wire connectors, snap out lamp sockets and lead wires to clock and ammeter.
8. The instrument cluster can then be removed.

Dodge 1960-61

1. Disconnect battery.
2. Cover front and back of speedometer lens with masking tape to prevent marring finish.
3. Remove instrument panel gear selector bezel.
4. Remove gearshift buttons and covers.
5. Remove steering column bracket on manual transmission equipped cars.
6. Loosen gearshift control housing and cable.
7. Remove gear selector bracket.
8. Disconnect speedometer cable.
9. With a long shank Phillips screwdriver, remove speedometer panel instrument housing.
10. Reverse above procedure to install.

①—Hydraulic lifter jobs having adjusting screws, see text for adjustment procedure.
②—Intake 30°, exhaust 45°.
③—Intake 29°, exhaust 44°.
④—High performance engines with mechanical lifters: valve lash .020″ hot.
⑤—Conventional adjustment.
⑥—"Silent Lash"—Clearance specified is obtained at valve stem tip with eccentric spring compressed. See text for details.
⑦—High performance 375 and 401 H.P. engines.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

Engine Section

ENGINE, REPLACE

Because of engine compartment tolerances, the engine should not be removed and installed with the transmission attached.

1. Drain cooling system and crankcase.
2. Remove radiator and air cleaner.
3. Remove hood.
4. Remove fuel and vacuum lines and all hoses, wires and linkage attached to engine.
5. Disconnect exhaust pipe from manifolds.
6. Remove starter and automatic transmission filler tube (if equipped).
7. Remove converter or flywheel housing lower cover.
8. Remove clutch release linkage (if equipped).
9. Support transmission with jack.
10. Unfasten converter or flywheel housing from engine.
11. Remove engine mounting bolts and lift engine out of chassis.

CYLINDER HEAD REPLACE

Service Note

In instances where cylinder head gasket leakage is hard to control, aluminum paint can be applied to the gasket as a sealer.

Spray one coat of the aluminum paint on both sides of the gasket and allow the paint to dry. Then spray a second coat on both sides and, while the paint is still wet, install the gasket. Torque the head and manifold bolts to specifications to complete the job.

V8-332, 352, 390 engines

Engine lubrication. V8-239, 272, 292 and 312 engines

Engine lubrication. V8-332, 352, 361, 390, 410 and 430 engines

1961-62 Ford & T-Bird 352, 390

1. Remove intake manifold, carburetor and radiator supply tank as an assembly.
2. Disconnect exhaust pipes from exhaust manifolds.
3. Remove bolts and lift off head.
4. Install cylinder heads in the reverse order of removal and tighten bolts in the sequence shown in Fig. 1 three times around. The final tightening should be done to the torque given in the *Engine Tightening* table.

1960-62 Ford V8-292

1. Remove intake manifold, carburetor, coil and radiator supply tank as an assembly.
2. Remove valve rocker arm shaft assembly. Remove and identify push rods to be sure they are returned to their original locations.
3. To remove the right-hand head, disconnect battery ground cable and oil level dipstick tube bracket.
4. Remove generator drive belt and move generator out of the way. Remove ignition harness bracket from head.
5. To remove left head, disconnect temperature sending unit wire and ground strap from head.
6. Remove distributor cap and spark plug wires at plugs.
7. Disconnect exhaust pipe from exhaust manifold.
8. Remove cylinder head bolts and lift off head.
9. Install heads in reverse order of removal and tighten bolts in the sequence shown in Fig. 1 three times around. Final tightening should be to the torque listed in the *Engine Tightening* table.

1961-62 Six

1. Drain cooling system and remove air cleaner.
2. Disconnect hoses, tubes, wires and linkage attached to head.
3. Remove coil, distributor cap and spark plugs.
4. On engine with positive crankcase ventilation, disconnect exhaust tube at regulator valve and crankcase outlet. Remove exhaust tube.
5. Remove valve rocker arm shaft assembly. Lift out push rods and identify them as to location so they can be installed in their original position.

V8-272, 292 and 312 engines

6. Unfasten and pull manifold away from cylinder head.
7. Remove radiator supply tank.
8. Remove all cylinder head bolts and lift head off engine.
9. Reverse removal procedure to install and tighten head in the sequence shown in Fig. 2 three times around. Final tightening should be to the torque listed in the *Engine Tightening* table.

Service Note

If a noise is encountered after the cylinder head is installed on six-cylinder engines, check for interference between push rod and push rod hole in cylinder head. If interference exists check push rod for straightness. If push rod is straight, then the cylinder head has not been aligned properly during its installation. The use of cylinder head guide pins (one at each end) on cylinder head installation will insure correct head alignment.

1958-60 Ford and T-Bird V8-332, V8-352

1. Drain cooling system.
2. Remove air cleaner.
3. Remove intake manifold and carburetor as a unit.
4. Remove exhaust manifolds and spark plugs.
5. If left head is to be removed, remove ignition coil.
6. Unfasten and remove cylinder head.
7. Install cylinder heads in the reverse

Fig. 1 Cylinder head tightening sequence. V8 engines

Fig. 2 Cylinder head tightening. Six cylinder engines

Six-cylinder overhead valve engine

order of removal. Tighten the heads in the sequence shown in Fig. 1 in three steps. Tighten the bolts first to 60-70 lb. ft., then to 70-80 lb. ft., and finally to 80-90 lb. ft. in the same sequence.

1959-60 V8-430 T-Bird

1. Remove intake manifold.
2. Remove coil and wire loom from left rocker arm cover.
3. Remove distributor
4. Remove valve push rod cover.
5. Remove rocker arm covers.
6. Rotate engine to bring No. 1 piston on T.D.C. on compression stroke. Continue rotation for 45° further. Then starting at No. 4 valve rocker support, loosen support bolts in sequence, two turns at a time. After bolts are all loosened, remove rocker arm assembly and then the push rods. Starting at No. 1 valve rocker support, follow same procedure on left support bolts.
7. Disconnect exhaust manifolds from pipes.
8. Unfasten and remove heads.
9. When installing, tighten head bolts in three progressive steps. First tighten bolts in sequence shown in Fig. 1 to 75 ft. lbs., then to 85 and finally to 95-105 ft. lbs.

1958-59 V8-292 Engine

1. Drain cooling system and remove air cleaner.
2. Remove intake manifold, carburetor and coil as a unit.
3. Remove rocker arm cover.
4. Remove exhaust manifolds.
5. To remove right head, disconnect battery ground cable and oil level dipstick tube bracket. Loosen generator mounting bolts and drive belt adjusting arm bolt at generator. Then pivot generator and remove drive belt. Loosen generator and move out of the way. Remove ignition harness bracket from head.
6. To remove left head, disconnect temperature sending unit wire and engine ground strap.
7. Release spring tension on rocker arms by loosening adjusting screws and remove rocker arm assembly. Remove and identify push rods so they can be replaced in their original positions.
8. Remove bolts and lift off head.
9. Reverse procedure to install head and tighten the bolts in the sequence shown in Fig. 1 in three steps. First tighten to 55 lb. ft., then to 65 lb. ft. and finally to 75 lb. ft. in the same sequence.

1958-60 Six

1. Drain cooling system.
2. Remove air cleaner and tape carburetor air horn closed.
3. Disconnect upper hose at radiator, heater hose at water outlet housing, oil pressure and water temperature sending unit wires at sending units, and battery ground cable at cylinder head.
4. Disconnect carburetor fuel inlet line and vacuum line at fuel pump, and distributor vacuum line at distributor.
5. Remove ignition coil and move it to one side.
6. Remove distributor cap and spark plugs.
7. On cars with automatic transmission, disconnect throttle control rod and accelerator connecting link at accelerator bracket. Remove accelerator bracket from block.
8. On cars with synchromesh transmission, disconnect accelerator rod at bell crank.
9. Disconnect fuel inlet line and distributor vacuum line at carburetor, and at intake manifold. Then remove three lines as an assembly.
10. Disconnect choke control cable at carburetor.
11. Remove rocker arm cover. Remove cap screw and bracket from No. 6 rocker arm support. Pull oil inlet line out of support and out of block with pliers.
12. Remove cap screw from No. 1 rocker arm support and remove oil outlet line and bracket.
13. Loosen all rocker arm adjusting screws to remove valve spring tension before removing rocker arm assembly.
14. Remove push rods and identify them so they can be installed in their original positions.
15. Unfasten and pull manifold away from cylinder head. Then unfasten and lift off head.
16. Reverse procedure to install the head and tighten it down in three steps in the sequence shown in Fig. 2. Tighten bolts first to 55 lb. ft., then

to 65 lb. ft. and finally to 75 lb. ft. in the same sequence.

1958-60 Edsel V8-332, 352, 361, E-400, E-475

1. Drain cooling system.
2. Remove rocker arms and push rods.
3. Remove intake manifold.
4. Remove ignition coil from the left cylinder if that particular head is being removed.
5. On E-400 and V8-361, disconnect wire from temperature gauge sending unit if the right cylinder head is being removed.
6. Unfasten exhaust pipe from manifold.
7. Unfasten and remove cylinder head and exhaust manifold as a unit. *The exhaust manifolds should not be separated from the cylinder heads unless the head is to be replaced or the valves are to be ground.*
8. Reverse the removal procedure to install and tighten the bolts in the sequence shown in Fig. 1 to the torque valves given in the *Engine Tightening* chart.

1955-57 V8

1. Drain cooling system.
2. Remove rocker arm cover.
3. Remove exhaust manifolds.
4. Remove spark plugs.
5. Remove intake manifold.
6. Remove ignition harness bracket.
7. On Thunderbird, remove distributor cap when removing right-hand cylinder head.
8. When removing the right cylinder head on all other vehicles, disconnect the battery ground cable and the oil dip stick tube bracket from the cylinder head.
9. Loosen and move the generator out of the way.
10. Release the spring tension on the rocker arms by loosening the adjusting screws, then remove the rocker arm assemblies and baffle plates.
11. Remove the push rods, keeping them in their order of removal for proper installation.
12. Disconnect wire from temperature sending unit in left cylinder head.
13. Remove the attaching bolts and lift off the heads.
14. Install heads in the reverse order of removal and tighten the bolts in the sequence shown in Fig. 1.

1955-57 Six

1. Drain cooling system and disconnect radiator and heater hose at cylinder head outlet elbow.
2. Disconnect windshield wiper vacuum line from manifold.
3. Remove air cleaner and disconnect battery cable at head, and accelerator rod and choke cable at carburetor.
4. Remove valve chamber cover.
5. Disconnect fuel line at fuel pump and carburetor and distributor vacuum line at distributor and carburetor.
6. Remove spark plugs.
7. Disconnect coil from head and allow coil to hang from distributor.

Fig. 3 Silent lash rocker arm operation. 1961-62 Six

8. Disconnect engine temperature sending unit wire.
9. Remove fan assembly.
10. Remove capscrew and clip from No. 6 rocker arm support bracket.
11. Pull oil feed line out of bracket and block.
12. Loosen all rocker arm adjusting screws to remove valve spring load from rocker arms.
13. Slide rocker arms away from push rods and remove rods. The rocker arms at each end of the engine cannot be moved so they should be left in place.
14. Tag the push rods so they can be reinstalled in the same place from which they were removed.
15. Unfasten the manifold and pull it away from the head, allowing it to be supported by the muffler inlet pipe.
16. Remove all cylinder head bolts. Install guide studs, and lift the head assembly off the engine.
17. Reverse the removal procedure to install the head and tighten it down in the sequence shown in Fig. 2.

VALVE ARRANGEMENT

V8-430 Left Bank	E-I-E-I-E-I-E-I
E-400	E-I-E-I-I-E-I-E
E-475 Right Bank	I-E-I-E-I-E-I-E
E-475 Left Bank	E-I-E-I-E-I-E-I

VALVES, ADJUST

Overhead Valve Engines

Prior to 1957, rocker arm adjusting screws are provided with a lock nut. Starting with 1957 engines self-locking adjusting screws are used.

If the cylinder head or rocker arm assemblies have been removed and installed, a preliminary (cold) valve lash adjustment should be made before starting the engine. If the adjustment is made in connection with an engine tune-up, the valve lash adjustment should be made with the engine at operating temperature.

To make the "hot" adjustment, operate the engine for a minimum of 30 minutes at a fast idle to stabilize engine temperatures. With the engine idling, check the valve lash with the proper feeler gauge between valve stem and rocker arm. Adjust the lash by means of the adjusting screw to the clearance given in the *Valve Specifications* table.

To make the "cold" adjustment, first turn over the engine to bring No. 1 piston up on its compression stroke, which will be indicated by the TDC mark on the vibration damper. Then proceed as follows:

Fig. 4 Aligning eccentric mark with valve stem. 1961-62 Six

Silent Valve Lash Mechanism, 1961-62

As shown in Fig. 3, the rocker arm eccentric functions throughout the rocker arm motion during the valve opening and closing cycle, compensating for expansion or wear of the valve train. Therefore, solid contact, "silent lash" between all parts of the valve train mechanism is maintained.

After removal or replacement of rocker arm or associated parts, the eccentrics are to be adjusted to their operating position in two steps: First to an initial adjustment and, second, to the final position. The initial position is accomplished with the engine shut off; the final adjustment is made with the engine running at normal idle speed. Adjustments for noise complaints and "out-of-position" eccentrics require only the final adjustment procedure.

In making the initial adjustment, position each piston at approximately T.D.C. of compression stroke and adjust the two associated rocker arms as follows:

1. Remove rocker arm cover.
2. Adjust rocker arm by pushing eccentric toward rocker arm until plunger is completely into its rocker arm bore, Fig. 4. Turn adjusting screw in until eccentric and plunger are held in the depressed position.
3. Slowly turn adjusting screw out until adjustment mark on eccentric is centered over valve stem, Fig. 5, and lock jam nut. Correct position of adjustment mark is shown in Fig. 6.
4. Repeat foregoing adjustment on remaining rocker arms, bringing the piston of each cylinder up on its compression stroke so that both valves are closed.
5. After all rocker arms have been adjusted, start engine and operate at normal idle speed. Observe position of adjustment mark on each eccentric.
6. Make minor adjustments as necessary with engine idling by turning adjusting screws in or out as necessary.
7. After adjustments have been completed, torque jam nuts to 35 ft. lbs., stop engine and install rocker arm cover.

1955-60 Six Cylinder

Make two chalk marks on the vibration damper. Space the marks approximately 120 degrees apart (⅓ of circumference) so that with the timing mark the damper is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat this procedure for the remaining set of valves, turning the crankshaft ⅓ turn at a time in the direction of normal rotation, while adjusting the valves in the firing order sequence, which is 153624.

V8-272, 292, 312

Make three chalk marks on the vibration damper. Space the marks 90 degrees apart (¼ of circumference) so that with the timing mark the damper is divided into four equal parts. Rotate the crankshaft until No. 1 piston is near TDC at the end of the compression stroke and adjust the following valves:

No. 1 intake and exhaust
No. 2 intake
No. 4 exhaust
No. 5 exhaust
No. 7 intake

Rotate the crankshaft 180 degrees (½ turn) which puts No. 4 piston on TDC. Then adjust the following valves:

No. 4 intake
No. 5 intake
No. 6 exhaust
No. 8 exhaust

Rotate the crankshaft 270 degrees (¾ turn), which puts No. 3 piston on TDC. Then adjust the following valves:

No. 2 exhaust
No. 3 intake and exhaust
No. 6 intake
No. 7 exhaust
No. 8 intake

V8-332, 352, 390 With Mechanical Lifters

Chalk mark the vibration damper into four equal parts as suggested above for other V8 engines. Then with No. 1 piston on TDC of its compression stroke, adjust the following valves:

No. 1 intake and exhaust
No. 4 exhaust
No. 5 exhaust
No. 7 intake
No. 8 intake

Rotate crankshaft 180 degrees (½ turn) which puts No. 4 piston up on TDC. Then adjust the following valves:

Fig. 5 Depressing valve rocker arm eccentric. 1961-62 Six

Fig. 6 Correct position of eccentric. 1961-62 Six

No. 2 exhaust
No. 4 intake
No. 5 intake
No. 6 exhaust

Rotate the crankshaft 270 degrees (¾ turn) which puts No. 3 piston on TDC. Then adjust the following valves:

No. 2 intake
No. 3 intake and exhaust
No. 6 intake
No. 7 exhaust
No. 8 exhaust

V8-332 and 352 With Rocker Arm Adjusting Screws and Hydraulic Lifters

These engines may be identified by a daub of orange paint on the engine front cover visible from the left side of the engine. In making an adjustment on these valves, follow the procedure outlined above for engines with mechanical lifters insofar as positioning the valves. Then proceed as follows:

1. With lifter being adjusted on base circle of cam on camshaft, turn adjusting screw so that clearance is obtained between push rod and rocker arm adjusting screw.
2. Adjust screw until clearance is just removed.
3. Tighten screw an additional 2½ turns.
4. Apply steady force to the push rod end of the rocker arm, depress the arm until the push rod bottoms in the lifter.
5. Check clearance between end of valve stem and rocker arm. A clearance of at least .060″ should exist. If less than .060″, back off the adjusting screw until at least .060″ clearance is obtained.
6. Repeat adjustment on all other valves in the sequence given for mechanical lifter jobs.

V8-332, 352, 390 With Non-Adjustable Hydraulic Lifters

For these engines a .060″ shorter push rod (color coded white) or a .060″ longer push rod (color coded yellow) are available for service to provide a means of compensating for dimensional changes in the valve mechanism. Valve stem-to-rocker arm clearance should be .078-.218″ with the hydraulic lifter completely collapsed. Repeated valve grind jobs will decrease this clearance to the point that if not compensated for the lifters will cease to function.

To check the clearance, bring the piston of the cylinder being checked on top dead center of the compression stroke. Then with hydraulic lifter collapsed, check the clearance between valve stem and rocker arm. If the clearance is less than .078″, the .060″ shorter push rod should be used. If clearance is more than .218″ the .060″ longer push rod should be used.

VALVES, REMOVE

V8 Engines

With the cylinder head removed as outlined previously, use a suitable valve spring compressor to compress each spring. Remove the valve locks and sleeve, tapping the sleeve with a soft hammer if necessary. Remove the neoprene sleeve from the valve stem and release the pressure on the spring. Remove the spring compressor and lift off the valve retainer sleeve, retainer, spring and valve. Repeat for the remaining valves. Keep the valves and related parts together so they may be installed in their respective positions if found in satisfactory condition.

Six Cylinder

After taking off the head as outlined previously, proceed as follows:

1. Remove capscrews retaining rocker shaft brackets to head and remove shaft assembly.
2. Clean carbon out of combustion chambers before removing valves.
3. Compress valve springs with a suitable spring compressor, remove valve stem locks and release the springs. Remove sleeve, valve spring cap retainer, spring and valve. Discard intake valve seals.
4. Place valves in a board with numbered holes so they can be replaced in their original positions upon reassembly.

Fig. 7A Checking valve spring installed height

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$″, otherwise the valve must be replaced.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

VALVE GUIDES

Overhead Valve Engines

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guides can be reamed oversize to accommodate one of three service valves with oversize stems (.003″, .015″ and .030″).

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004″ on the intake or .005″ on the exhaust, ream the valve guides to accommodate the next oversize diameter valve.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 7A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if

Fig. 8 Checking valve spring pressure

shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}$″ to $\frac{5}{64}$″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 8, and according to the specifications given in the *Valve Data Chart.* If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

ROCKER ARMS

To disassemble the rocker arms, re-

Fig. 9 Six cylinder rocker arm shaft assembly

move cotter pins from each end of the shaft and remove the flat washers and spring washers. Slide rocker arms, springs and supports off shaft, being sure to identify all parts so they can be assembled in the same position.

If it is necessary to remove the plugs from each end of the shaft, drill or pierce one plug, then insert a steel rod through the plug and knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Assemble the rocker arms and related parts as indicated by Figs. 9, 10 and 11.

HYDRAULIC VALVE LIFTERS

The internal parts of each hydraulic valve lifter assembly are a matched set. If these are mixed, improper valve operation may result. Therefore, disassemble, inspect and test each assembly separately to prevent mixing the parts.

Fig. 12 illustrates the type of hydraulic lifter used. See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method of locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Press one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

To disassemble, first immerse the lifters in solvent and remove all traces of carbon and varnish. Remove the lock ring from the lifter body and disassemble as shown in Fig. 12. Wash all parts in solvent and wipe dry with a lint-free cloth.

To assemble, hold the plunger inverted and assemble the valve disc, small spring, valve disc retainer and large spring on the plunger. Slip the body over the plunger, then install the push rod cup and lock ring in the body.

TIMING CASE COVER

1959-60 V8-430 T-Bird

1. Remove hood, air cleaner, radiator, radiator supply tank, fuel pump and fuel pump push rod.
2. Remove water pump, pulley and fan.
3. Remove vibration damper.
4. Remove engine right and left support-to-underbody nuts. Raise engine with jack and wood block placed under oil pan. Position one-inch wooden blocks between engine front support brackets on underbody and block. Then remove jack from under oil pan.
5. Remove oil pan.
6. Unfasten and remove cover.

1958 T-Bird & 1959-60 V8-352 T-Bird

1. Drain cooling system and crankcase.
2. Remove hood, air cleaner, radiator, fuel pump, radiator supply tank, water pump, vibration damper and oil pan.
3. Unfasten and remove cover.

Fig. 10 Rocker arm shaft assembly. V8-332, 352, 361, 390, 410 and 430 engines

Fig. 11 Rocker arm shaft assembly. V8-272, 292 and 312 engines

V8-332, 352, 361, 390, 410

1. Remove radiator and fuel pump.
2. On cars with power steering, disconnect pump bracket from water pump.
3. Remove water pump.
4. Remove vibration damper with puller.
5. Unfasten and remove front cover. *If oil pan gasket is broken or damaged in removing cover, remove oil pan and install new gasket.*
6. Install a new cover oil seal and reinstall the cover in the reverse order of removal.

V8-272, 292, 312

1. Remove radiator and fuel pump.
2. Remove vibration damper.
3. Unfasten front cover from block and oil pan and remove cover and water pump as a unit. *If the oil pan gasket is broken during removal of front cover, remove oil pan and install new gasket.*
4. Install a new cover oil seal and reinstall cover in reverse order of removal.

1956-62 Six Cylinder

1. To remove cover, drain cooling system and oil pan.
2. Disconnect transmission oil cooler lines (if equipped).
3. Remove radiator, fan, belt and pulley.
4. If equipped, remove power steering pump belt, and pump pulley from crankshaft.
5. Remove vibration damper.
6. Remove oil pan as outlined further on.
7. Remove water pump.
8. Unfasten and remove front cover.
9. Install new seal in cover. Then reverse removal procedure to install cover.

1955 V8

1. To remove the cover, drain cooling system and remove radiator.
2. Loosen fan blades and hub.
3. Remove fuel pump.
4. Remove fan belt.
5. Unfasten generator mounting bracket and move it out of the way.
6. Loosen generator adjusting bracket and move it out of the way.
7. Remove crankshaft pulley.
8. Remove engine front steady rest.
9. Remove four bolts that fasten front cover to oil pan.
10. Disconnect water by-pass tube.
11. Remove seven remaining front cover bolts then remove the water pump and front cover as a unit.
12. Install a new front cover oil seal if necessary and reinstall the cover in the reverse order of its removal.

1955 Six

To remove the front cover, take off the radiator and vibration damper. Remove the two screws which fasten the oil pan to the front cover and loosen the other oil pan screws slightly. Remove the remaining cover screws and take off the cover and gasket.

Install a new cover oil seal and reinstall the cover in the reverse order of its removal, being sure to tighten the oil pan screws.

TIMING CHAIN

V8-332, 352, 361, 390, 410

1. To remove the chain, first take off the front cover as outlined previously.
2. Crank engine until timing mark on camshaft sprocket is adjacent to timing mark on crankshaft sprocket, Fig. 14.
3. Remove camshaft sprocket cap screw and fuel pump eccentric.
4. Slide both sprockets and chain forward and remove as an assembly.
5. Reverse foregoing procedure to install the chain, being sure to align the timing marks as shown.

V8-272, 292, 312

To remove the chain and sprockets, take off radiator, fan blades and hub, timing chain cover and oil pan. Remove camshaft sprocket capscrew and lockwasher. Remove fuel pump eccentric and counterweight from camshaft.

Crank the engine until timing marks on the sprockets and chain are positioned as shown in Fig. 15. Slide both sprockets and chain forward and remove them.

To install, position the chain and camshaft sprocket on the camshaft. Be sure the timing marks are positioned as

Fig. 12 Hydraulic valve lifter disassembled

Fig. 14 Timing Marks lined up for correct valve timing. V8-332, 352, 361, 390, 410, 430

shown in Fig. 15. Install the other parts removed.

1955 V8

Remove the front cover, water pump and fan as a unit. Crank the engine until the timing marks on the sprockets are positioned as shown in Fig. 15. Remove the fuel pump eccentric and camshaft sprocket cap screw. Remove the eccentric and counterweight from the camshaft. Slide both sprockets and the chain forward, and remove the camshaft sprocket and chain and a unit.

To install, position the chain and camshaft sprocket on the camshaft. Be sure the timing marks are positioned as shown in Fig. 15. Install the other parts removed.

Six Cylinder Engines

To make the sprocket and chain accessible, remove the radiator, vibration damper and cylinder front cover. Before removing the crankshaft sprocket, align the timing marks as shown in Fig. 16. Remove the camshaft sprocket retaining bolt and washer. Slide the camshaft sprocket, timing chain and crankshaft sprocket forward until the camshaft sprocket comes off the camshaft.

To install, place the chain over the crankshaft sprocket and insert the camshaft sprocket in the chain so the timing marks on both sprockets are aligned as shown in Fig. 16. Align the keyway in the camshaft with the camshaft sprocket keyway and slide the assembly into position.

CAMSHAFT, REPLACE

1960-62 Ford & Edsel Six

1. Remove timing chain cover and oil pan.
2. On 1961 remove headlamp trim rings.
3. Remove grille. On 1962 remove grille and grille center support.
4. Remove rocker arm assembly.
5. Remove push rods.
6. Remove distributor.
7. Remove push rod cover. Raise valve lifters clear of camshaft lobes and secure them with spring-type clothes pins or window regulator clips.
8. Remove fuel pump.
9. Remove timing chain and sprockets.
10. Remove camshaft thrust plate and spacer.
11. Slide camshaft out of engine.

Fig. 16 Valve timing. Six cylinder

1960-62 Ford & Edsel V8-292

1. Remove timing chain cover and water pump as an assembly.
2. Remove intake manifold and oil pan.
3. Remove grille. On 1962 remove grille and grille center support.
4. Remove rocker arm assembly.
5. Remove push rods.
6. Remove distributor.
7. Remove timing chain and sprockets.
8. Raise valve lifters clear of camshaft lobes and secure them with spring-type clothes pins or window regulator clips.
9. Remove camshaft thrust plate and spacer.
10. Slide camshaft out of engine.

1960-62 Ford V8-352, 390

1. Remove timing chain cover, chain, sprockets and intake manifold.
2. Remove grille and distributor.
3. Remove rocker arm assembly.
4. Remove push rods.
5. Position an inspection light through push rod opening and into valve push rod valley. Remove valve lifters with a magnet through push rod openings. *It may be necessary in some cases to transfer the lifter over to an adjoining push rod opening in order to remove it.*
6. Remove oil pan.
7. Slide camshaft out of engine.

1958-60 Edsel V8 (Exc. 292)

1. Remove timing chain cover, chain and sprockets.
2. Remove intake manifold.
3. Remove push rod cover.
4. Remove valve lifters.
5. On 1958 with 410 engine remove vertical mesh grille.
6. Slide camshaft out of engine.

1959-60 V8-352 T-Bird

1. Remove radiator, radiator supply tank and hood.
2. Remove vibration damper, timing case cover, chain and sprockets and intake manifold.
3. Remove hydraulic lifters.
4. Remove camshaft.

1959-60 V8-430 T-Bird

1. Remove hood, radiator, radiator supply tank and grille.

Fig. 15 Timing marks lined up for correct valve timing. V8-272, 292, 312.

2. Remove vibration damper, timing case cover, chain and camshaft sprocket and oil pan.
3. Remove distributor.
4. Remove rocker arm assemblies and push rods.
5. Remove hydraulic valve lifters with a magnet through the valve push rod holes in cylinder heads.
6. Remove camshaft.

1959-60 V8-332 Ford

1. Remove air cleaner, radiator, water pump, vibration damper, fuel pump and timing case cover.
2. Unfasten power steering pump and lay it on front engine splash shield.
3. Remove camshaft sprocket and chain.
4. Remove coil and distributor.
5. Disconnect transmission linkage.
6. Remove rocker arms and push rods.
7. Remove intake manifold and carburetor.
8. Remove baffle from push rod chamber and lift hydraulic lifters from block.
9. Withdraw camshaft from engine.

1958-60 Thunderbird

1. Remove timing chain cover and chain as outlined previously.
2. Remove intake manifold and valve lifters.
3. Remove retaining bolts from top center of grille and three bolts from bottom of grille and push top of grille forward.
4. Remove the camshaft.

1958 V8-332 Ford

1. Drain cooling system and oil pan.
2. Remove intake manifold and carburetor as an assembly.
3. Remove radiator, fuel pump and drive belts.
4. Remove water pump, fan and pulley as an assembly.
5. Remove timing case cover, stabilizer bar, oil pan and oil pump.
6. Crank engine until timing marks are positioned as shown in Fig. 14. Then remove timing chain and sprockets.
7. Remove valve lifters and camshaft.
8. Reverse removal procedure to install.

Fig. 17 Piston and rod assembly. All V8's

Fig. 18 Correct assembly of piston and rod. Six cylinder

1958-59 V8-292, 1956-57 V8

1. Drain cooling system and oil pan.
2. Remove intake manifold, carburetor and ignition coil as an assembly.
3. Remove radiator (also grille support on 1956), fuel pump, fan, spacer, pulley, vibration damper, timing case cover, stabilizer bar and oil pan.
4. Crank engine to bring timing marks in position shown in Fig. 15.
5. Remove distributor cap and scribe a line on the distributor housing and cylinder block to mark the position of the rotor and distributor housing for installation. Then remove distributor.
6. Remove timing chain and sprockets.
7. Remove rocker arm assemblies, push rods and push rod chamber cover.
8. Turn camshaft until valve lifters can be lifted with the fingers or with a magnet. Raise lifters clear of camshaft lobes and hold them up with spring-type clothes pins.
9. Carefully remove camshaft by pulling it forward out of engine.
10. Reverse removal procedure to install.

1956-59 Six

1. Drain cooling system and oil pan.
2. Remove radiator and grille (also grille support bar on 1956-57).
3. Remove fan, belt(s), pulley, vibration damper and water pump.
4. Remove oil level dipstick, crankcase ventilation tube, stabilizer bar on 1957-59, flywheel housing inspection cover and oil pan.
5. Remove rocker arms and push rods.
6. Remove distributor cap.
7. Remove push rod cover.
8. Remove fuel pump. Crank engine to line up timing marks as shown in Fig. 16.
9. Scribe a line on distributor housing and cylinder block to mark position of rotor and distributor housing for installation. Then remove distributor.
10. Remove timing chain and sprockets.
11. Turn camshaft until valve lifters can be raised and secured with spring-type clothes pins.
12. Slide camshaft out of engine.
13. Reverse removal procedure to install.

1955 V8

1. Remove radiator, radiator grille, crankshaft pulley, fuel pump, water pump and fan blade assembly and timing case cover.
2. Remove intake manifold, carburetor and ignition coil as a unit.
3. Remove rocker arm assemblies and push rods.
4. Crank engine until timing marks on sprockets are aligned as shown in Fig. 15 depending upon the type of chain used.
5. Remove distributor cap and scribe a line on the distributor housing and cylinder block to mark the position of the rotor and distributor housing. Then remove distributor.
6. Remove camshaft sprocket and timing chain.
7. Remove camshaft thrust plate, key and spacer ring.
8. Use a magnetic lifter to lift the tappets and install clothes pins or other suitable holders to keep the tappets up.
9. Carefully remove the camshaft by pulling it toward the front of the engine.
10. Reverse the foregoing procedure to install the camshaft.

1955 Six

To remove the camshaft, take off the radiator. Remove the crankshaft damper and timing case cover. Remove the rocker arm cover and valve push rod covers. Lift the tappets and hold them up with clothes pins or rubber bands.

Note—If the engine is removed from the vehicle and mounted on a work stand, position it front end up and pull the tappets away from the camshaft to facilitate camshaft removal. Be sure the oil pan is

Fig. 19 Piston clearance chart

either drained or removed before inverting engine.

Take off the distributor, fuel pump, camshaft sprocket and timing chain. Remove the screws retaining the camshaft thrust plate and take off the plate. Then carefully pull the camshaft out of the engine.

CAMSHAFT BEARINGS

When necessary to replace camshaft bearings, the engine will have to be removed from the vehicle and the plug at the rear of the cylinder block will have to be removed in order to utilize the special camshaft bearing removing and installing tools required to do this job. If properly installed, camshaft bearings require no reaming—nor should this type bearing be reamed or altered in any manner in an attempt to fit bearings.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

Fig. 20 Checking bearing clearance with Plastigage

PISTON & ROD, ASSEMBLE

All V8's

Assemble the pistons to the rods as shown in Fig. 17.

All Sixes

Piston heads are marked for location on the forward side, Fig. 18. Rods and caps are numbered on the same side as the piston they serve.

PISTONS

Pistons are available for service replacement in standard sizes and oversizes of .005", .020", .030", .040" and .060".

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in a clean solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

New pistons should be fitted according to the recommendations given in Fig. 19.

PISTON PINS

All V8's (Except 430)

It is recommended procedure to replace piston pins whenever new rings are installed. Pins that have been relatively quiet when the old rings were in service may be noisy after new rings are installed.

Use a suitable reamer to ream the piston for oversize pins. The pins are retained by snap rings, one located at each end of the pin. When installing the retainers, make sure each one enters the groove in the piston pin boss.

T-Bird V8-430 Engine

Piston pins in these engines are a pressed fit in the piston, no snap rings being used to retain the pin in the piston. Pistons and pins are furnished by Ford only as an assembly.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the

new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 20. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

1959-60 Ford & T-Bird Service Note

A new connecting rod bolt, identified by a small projection at the center of the bolt head, is available to replace an obsolete type used in certain 1959-60 engines. When performing service operations that require removing the connecting rod bolts from one of these engines, all bolts should be checked, and any bolt that does not have the projection should be replaced with the new type.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque valve given in the *Engine Torque Specifications* table.

CRANKSHAFT OIL SEAL

V8-272, 292, 312

Oil sealing at the rear of the crankshaft is obtained by a wick-type seal half in the block and a similar seal fitting into the groove of the seal retainer for the lower half. Seals are also used in the vertical grooves in the sides of the seal retainer.

When necessary to install new seals, press the seal half in the block and seal retainer and cut the ends of the seals flush. Coat the seal retainer-to-block mating surface with sealer, install the retainer and tighten the bolts to a torque of 23-28 ft. lbs.

Dip the retainer side seals in light engine oil, then immediately install them in the grooves. It may be necessary to tap the seals into place for the last ½″ of travel. *Do not cut the seal projecting ends, and do not use sealer on the side seals as they are designed to expand when dipped in oil.*

Check the retainer side seals for leaks by squirting a few drops of oil into the parting lines between the retainer and cylinder block from the outside. Blow compressed air against the seals from the inside of the block. If air bubbles appear in the oil, it indicates possible oil leakage.

The foregoing test should *not* be performed on newly installed side seals until sufficient time has been allowed for the seals to expand in the grooves.

6-223, V8-332, 352, 361, 390, 410, 430

Oil sealing at the rear of the crankshaft is obtained by seal halves in the cylinder block and rear bearing cap. Side seals are also used in the vertical grooves in the bearing cap. Install and test seals in the same manner outlined for other models above.

OIL PAN, REPLACE

1960-62 Ford & Edsel Six

1. Drain crankcase.
2. Remove flywheel housing lower cover and oil level dipstick.
3. On Station Wagons, unfasten stabilizer bar from lower control arm and frame and position the bar as far forward as possible.
4. On engines with vent tube type crankcase ventilation system, remove ventilation tube.
5. Remove oil pan bolts and turn crankshaft as required to gain clearance to remove the pan.
6. After removing the pan, remove oil pump inlet tube and screen.

1960-62 Ford & Edsel V8-292

1. Drain crankcase and disconnect oil pump inlet tube at oil pump.
2. Remove oil pan retaining bolts and drop pan.
3. Remove nut securing inlet tube to oil pan; then remove screen and inlet tube from pan.

1960-62 Ford V8-352, 390

1. Drain oil from crankcase and remove oil level dipstick.
2. Remove flywheel housing lower cover.
3. Unfasten and lower oil pan to frame crossmember.
4. Crank engine to obtain necessary clearance between crankshaft counterweight and rear of oil pan.
5. If oil pump is to be removed, remove retaining bolts and allow pump to fall into oil pan. If pump is not to be removed, loosen pump inlet tube upper bolt and remove lower bolt; then swing inlet tube clear of pan.
6. Remove oil pan by bringing it forward and tilting it down.

1958-60 Edsel V8 (Exc. 292)

1. Crank the engine to place the No. 1 or 5 piston on top dead center.
2. Remove oil level dipstick.
3. Drain crankcase.
4. Remove stabilizer bar.
5. Unfasten front engine mounts and raise engine approximately two inches and block it in this position.
6. Remove oil pan retaining bolts. Then lower pan and allow it to set on the frame crossmember.
7. Reach into the crankcase and remove the two bolts that attach the oil pump screen pickup tube to the pump. Allow the screen and tube assembly to drop into the oil pan.
8. Move oil pan forward and lower it from chassis.

1959-60 V8-430 T-Bird

1. Crank engine until the 14° mark on the vibration damper is aligned with the timing pointer.
2. Drain oil pan.
3. Remove engine right and left front insulators.
4. Remove engine right and left support-to-underbody nuts. Raise engine with a jack and wood block placed under oil pan. Position a one-inch wood block between engine front support brackets and underbody. Remove jack from under oil pan and allow engine to rest on blocks.
5. Unfasten and lower oil pan to underbody crossmember.
6. Remove oil pump inlet tube and

screen lower retaining screw and loosen upper screw so that inlet tube can swing freely.
7. Remove oil pan in a lowering forward motion.

1958 T-Bird & 1959-60 V8-352 T-Bird, 1961-62 T-Bird

1. Drain cooling system and crankcase.
2. Disconnect radiator upper hose.
3. Unfasten and lower oil pan to underbody cross member.
4. Position crankshaft so that counterweight will clear pan and move pan forward.
5. If necessary, position ignition coil out of the way.
6. Install engine lifting sling.
7. Remove engine front mounting bolts.
8. Raise engine high enough to permit removal of oil pump bolts.
9. Remove oil pan and pump.

1958-60 V8-332, 352 Ford

1. Crank engine to bring No. 1 piston up on TDC to obtain necessary clearance between crankshaft counterweight and rear of oil pan.
2. Remove stabilizer bar (1958).
3. Unfasten oil pan and lower it to frame cross member.
4. Loosen oil pump inlet tube upper bolt and remove lower bolt. Swing inlet tube clear of oil pan. Remove pan by bringing it forward and tilting it down.

1957 V8 Ford & 1958-59 Ford & Edsel V8-292

1. Drain oil from crankcase.
2. On 1958-59 car, remove stabilizer bar.
3. Disconnect oil pump inlet tube at oil pump.
4. Remove screws and oil pan.

1957-59 Ford & Edsel Six

1. Remove oil level dipstick, stabilizer bar and flywheel housing inspection cover.
2. Unfasten and remove oil pan.

1956 V8

1. To remove the pan, drain crankcase and remove oil level indicator.
2. Remove engine front splash pans (except Thunderbird).
3. On Fordomatic cars, remove converter housing cover.
4. Disconnect oil inlet tube at oil pump.
5. Remove O-ring seal from pump end of tube.
6. Remove attaching screws and lower pan. *On all cars except Thunderbird, No. 5 piston must be at the top of its cylinder before pan can be removed.*

1955 V8

To remove the oil pan, drain the crankcase and remove the front engine splash pans (except on Thunderbird). Take off the oil pump-to-oil pan pipe. On 1954 Fordomatic cars only, remove converter housing dust cover. Turn engine over to bring No. 1 piston up on top dead center. Then remove the attaching bolts and take down the pan.

1956 Six

To remove the oil pan, drain crankcase and remove oil level indicator. Remove engine left and right splash aprons. Remove flywheel housing inspection cover. Remove retaining screws and take down pan.

1955 Six

1. To remove the pan, drain crankcase and remove oil dip stick.
2. Drain cooling system and disconnect upper hose at engine.
3. Remove engine front support bolts.
4. Remove engine steady rest.
5. Raise front of engine about 2".
6. Remove right and left engine front splash aprons.
7. Lower engine on a suitable block.
8. Remove flywheel housing cover.
9. Unfasten and remove oil pan.

OIL & VACUUM PUMP

1959-60 V8-430

A vacuum pump is integral with the oil pump and is used as a booster for windshield wiper operation. If the vacuum section of the pump is damaged replace it with a new unit.

The oil pump is the rotor type and is serviced as described below.

OIL PUMP REPAIRS

Rotor Type Pump, Fig. 22

1. With all parts clean and dry, check the inside of the pump housing and the outer race and rotor for damage or excessive wear.
2. Check the mating surface of the pump cover for wear. If this surface is worn, scored or grooved, replace the cover.
3. Measure the clearance between the outer race and housing. This clearance should be .006-.009".
4. With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and housing. Measure the clearance between the straight edge and the rotor and outer race. Recommended limits are .001-.0035". *The outer race, shaft*

Fig. 22 Rotor type oil pump

Fig. 23 Gear type oil pump

Fig. 24 Water pump. V8-332, 352, 361, 390, 410, 430

Fig. 25 Water pump. V8-272, 292, 312

Fig. 27 Six cylinder water pump

and rotor are furnished only as an assembly.

5. Check the drive shaft-to-housing bearing clearance by measuring the O.D. of the shaft and the I.D. of the housing bearing. The recommended clearance limits are .0015-0029″.
6. Inspect the relief valve spring for a collapsed or worn condition.
7. Check the relief valve piston for scores and free operation in the bore. The specified piston clearance is .0015-.0029″.

Gear Type Pump, Fig. 23

After all parts are clean and dry, inspect the pump body and gear teeth for damage or wear. Check the gear end clearance with a dial indicator or Plastigage. The Plastigage method is as follows:

Position the gasket on the housing, then place a strip of Plastigage on the gears and install the cover. Remove the cover and check the Plastigage reading. The clearance is .0015-.006″.

Check the gears for freedom of rotation. Inspect the relief valve spring for a collapsed or worn condition. Check the relief valve piston for scores and free operation in the bore.

RADIATOR

1960-62 Ford

1. Drain cooling system and disconnect upper and lower hoses at radiator.
2. Disconnect automatic transmission fluid cooler lines at radiator.
3. Remove radiator retaining bolts at upper support and loosen bolts at lower support. Remove fan guard upper retaining bolts.
4. Remove radiator, upper supports and fan guard as an assembly.

1958-62 Thunderbird

1. Disconnect oil cooler lines at radiator (if used).
2. On 1961-62, remove fan shroud.
3. On 1958-60, remove fan and spacer if equipped, then disconnect upper and lower hoses at radiator.
4. Unfasten radiator support bolts and lift out radiator. The radiator supply tank need not be removed unless necessary.

1958-60 Ford & Edsel

1. Drain cooling system and disconnect upper and lower radiator hoses.
2. On V8 cars with automatic transmission, disconnect oil cooler lines at radiator.
3. Unfasten radiator from its support and remove it from the chassis.
4. When installing the radiator on V8 cars with automatic transmission do not tighten the support bolts until after the oil cooler lines are connected.

1955-57 Except Thunderbird

To remove the radiator, drain cooling system and remove upper and lower hoses. On 6-cylinder cars, remove radiator support cross bar. On all models, unfasten radiator from its support and lift it out of the vehicle.

1955-57 Thunderbird

To remove the radiator, raise the front of the vehicle and position safety stands. Drain cooling system and remove water hoses. On 1956-57, remove fan lower shroud. Unfasten the radiator from its support and lift out the radiator and shroud as a unit.

WATER PUMP, REPLACE

1960-62 Ford & Edsel Six

1. Drain cooling system and disconnect hoses at pump.
2. Remove fan, pulley and drive belt.
3. Remove water pump back plate bolt which retains radiator supply tank support bracket and generator bracket.
4. Unfasten and remove pump.

1960-62 Ford & Edsel V8-292, 352, 390

1. Drain cooling system and disconnect hoses from water pump.
2. Remove fan, belt and pulley (also spacer on 292 engine).
3. Remove bolts retaining pump to cylinder front cover (V8-292) or to block.
4. Remove pump from engine.

1958-59 Edsel V8

1. Drain cooling system and disconnect hoses from pump.
2. Remove drive belts, fan and pulley (also spacer on V8-410).
3. Slide front pump hose clamp rearward and remove pump from engine.

Fig. 29 Ignition details. V8-272, 292, 312

Fig. 30 Ignition details. V8-332, 352, 361, 390, 410, 430

1958-62 Thunderbird

Remove fan belt. Disconnect radiator lower hose and heater hose at water pump.

On 352 and 390 engines, loosen fuel pump bolts and slide pump out of bolts one inch for access to the water pump lower left retaining bolt.

Loosen and move generator bracket away from water pump. Then unfasten and remove pump from engine.

1958-59 V8 Ford

Drain cooling system and disconnect radiator lower hose and heater hose at water pump. Remove fan, belt and pulley (also fan spacer on V8-292). Unfasten pump and remove it from the engine.

1955-57 V8

To remove the pump, drain the cooling system and disconnect the lower radiator hose and heater hose. Remove the fan belt, fan, spacer and pulley. Unfasten the pump from the timing case cover and lift out the pump and timing pointer.

On Thunderbirds, it will be necessary to remove the engine left-hand splash shield. Also the generator support bracket must be moved out of the way.

1955-59 Six

Drain the cooling system and disconnect the lower radiator hose and heater hose. Remove the fan belt and fan. Unfasten the pump from the engine and lift it off.

WATER PUMP REPAIRS

These water pumps, Figs. 24 to 27, are of the sealed type and repair kits are available for making repairs.

To disassemble, remove the snap ring from the groove in front of the pump housing, directly behind the pulley. Remove the pulley and, with a suitable puller, press the shaft out of the impeller. Press the bearing assembly from the pump housing. Press seal and sleeve assembly from pump housing. The snap ring in the center of the housing need not be removed unless damaged.

When assembling the pump, be sure to maintain the clearances listed below between the impeller and pump housing.

1955-59 Six	.020-.030″
1955-59 Ford V8	.030-.040″
1958-59 V8-410	.105-.115″
1958-59 V8-430	.095-.105″
1960 Six	.030-.040″
1960 V8-292	.030-.040″
1960 V8-332, 352, 361	.080-.090″
1961-62 Six	.015-.025″
1961-62 V8-292	.025-.035″
1961-62 V8-352, 390	.070-.080″

DISTRIBUTOR, REPLACE

Removal

1. To remove the distributor, disconnect the primary wire and vacuum control pipe. On some models the work may be made easier if the accelerator pull back spring is disconnected.
2. Remove distributor cap.
3. Scribe a mark on the distributor body indicating the position of the rotor, and scribe another mark on the body and engine block indicating position of distributor body in block. These marks can be used as guides when installing distributor in a correctly timed engine.
4. Remove hold down screw or screws and lift distributor out of block. *Do not crank engine while distributor is removed or the initial timing operation will have to be performed.*

Installation

If the crankshaft has not been disturbed, install the distributor, using the scribed marks previously made on the distributor body and engine block as guides.

If the crankshaft has been rotated while the distributor was removed from the engine, it will be necessary to retime the engine. Crank the engine to bring No. 1 piston on top dead center of its compression stroke. Align the timing mark on the vibration damper or pulley with the timing pointer (see *Tune Up*) chart). Install the distributor so that the rotor points to the No. 1 spark plug wire terminal in the distributor cap, Figs. 28, 29, 30.

Note—On all overhead valve engines, make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is properly engaged, in order to engage the oil pump intermediate shaft.

IGNITION TIMING

All Models

Align the distributor rotor with No. 1 spark plug wire terminal in the distributor cap, when No. 1 piston is on the compression stroke and timing mark on the crankshaft pulley or vibration damper and pointer are aligned (see *Tune Up* chart).

With the timing mark in line with the pointer, the distributor points should just start to open. It may be necessary to rotate the distributor body clockwise slightly and then counter-clockwise until the points just start to open. Tighten the distributor lock plate screw.

Start the engine and check the timing with a timing light.

Using Timing Light

When using a power timing light, *be sure to disconnect the distributor vacuum line before checking timing,* otherwise the timing will be affected due to the fact that the vacuum opening is above the throttle plate.

Connect the timing light high tension lead to the No. 1 spark plug and the other two leads to the proper battery terminals. Clean the dirt from the timing mark and if necessary use white chalk to make the mark more visible.

Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark does not line up as the light flashes, rotate the distributor as required to bring them in alignment.

STARTER REPLACE

1955-62 Ford & T-Bird

Disconnect cable at starter terminal. Remove clutch housing-to-starter screws and remove starter. It may be necessary to tilt the starter slightly to clear the starter drive around the flywheel.

1958-60 Edsel

1. Disconnect battery ground cable.
2. Raise vehicle.
3. Disconnect cable from starter.
4. On some models additional clearance is required to remove starter. If so, unfasten steering idler arm bracket from frame and lower linkage. Unfasten right-hand exhaust pipe from manifold, pry pipe downward until it clears studs, then move pipe to right as far as possible.
5. Unfasten starter from flywheel housing.
6. Move starter forward and downward past steering linkage and exhaust pipe.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked during vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Do not use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

HOLLEY NOTES

Fig. ①—Float level measured from roof of float chamber to lowest point of float with carburetor inverted.

Fig. ②—Fuel level measured from power valve mounting surface.

Fig. ③—Float level measured from floor of fuel bowl to bottom of float with fuel bowl inverted.

Fig. ④—Float level measured from machined surface of main body to top of free end of float with float in uppermost position.

Fig. ⑤—Float level measured from air horn gasket to bottom of float with air horn inverted.

⑥—With engine running at hot idle speed, loosen dashpot screw. Hold throttle closed and depress dashpot plunger fully. Turn dashpot in its bracket as required to obtain the specified clearance between plunger and accelerator lever.

⑦—Stop engine after having been warmed up to operating temperature. Then remove sight plug. Fuel within bowl should be at lower edge of sight plug hole. Adjust by loosening lock screw on top of fuel bowl just enough to allow rotation of nut. Adjust as required and tighten screw.

⑧—Bend vent rod at angle as required to obtain specified clearance between vent button and machined surface of fuel bowl with throttle in hot idle position.

⑨—With hot idle speed properly adjusted, turn fast idle screw in until it just touches lowest step on fast idle cam; then back off one turn.

⑩—With engine stopped, fuel within bowl should be at lower edge of sight plug hole. Raise or lower float as required to obtain proper fuel level (see ③).

⑪—Below centerline of main discharge nozzle.

⑫—With throttle plates closed, clearance between vent button and top of fuel bowl should be as specified. Adjust by bending horizontal arm on accelerating pump operating lever.

⑬—With engine running at normal operating temperature, fuel level is correct if fuel just dribbles out of both sight plug holes. If not, adjust both floats.

⑭—Measured from bowl cover upper screw. Primary 1/2", secondary 5/8".

⑮—Below machined surface of float bowl.

⑯—With throttle fully closed, hold dashpot plunger in to the limit of its travel. Then turn adjusting screw as required to obtain the specified clearance between screw and plunger.

⑰—With throttle plates held wide open, there should be the clearance listed between pump arm and hex nut on accelerating lever with pump held fully depressed. To adjust, hold hex nut and turn adjusting screw as required.

⑱—With fast idle screw on highest step of fast idle cam.

⑲—Turn fast idle adjusting screw in until it just touches lowest step on fast idle cam.

Fig. ⑳—Invert fuel bowl. Then loosen lock screw enough to allow adjusting nut to rotate. Turn adjusting nut until base of float is parallel with floor of bowl. Adjust both floats in same manner.

Fig. ㉑—With engine idling, turn adjusting nut as required until fuel just dribbles out of sight plug hole. Adjust both floats in same manner.

Fig. ㉒—With fast idle screw in contact with high step of cam, adjust screw to open primary throttle plates the dimension listed (side toward center of carburetor).

Fig. ㉓—Seat screw lightly and back it off one full turn. Final adjustment is made with engine running at normal operating temperature.

HOLLEY NOTES
continued

Fig. ㉔—This adjustment eliminates idle instability due to icing. Turn screw in until it seats lightly, then back it off one full turn.

Fig. ㉕—This adjustment is important in high temperature operation. With throttle closed, center of valve should clear bowl by the dimension specified. Adjust by changing the arc in rod near contact with throttle lever.

Fig. ㉗—Hold choke plate closed and throttle wide open. Clearance from back of choke plate to back of main body should be as specified. Adjust by bending unloader lever.

Fig. ㉖—With both throttles held wide open and pump held down, clearance between nut and pump lever should be as specified.

FORD CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

FORD NOTES

Fig. ①—Float level measured from top surface of main body to top of free end of float with float in uppermost position.

②—Pump lever has four holes and pump link has two holes to control pump stroke. Install pump rod in top hole for winter operation, and second hole from bottom for summer operation. Install pump operating rod in outside hole in pump link.

③—With fast idle screw on high step of fast idle cam.

④—Turn fast idle screw in until it just touches the lowest step on fast idle cam. Then back off 1/4 to 1/2 turn.

⑤—With engine at normal operating temperature and hot idle speed properly adjusted, loosen dashpot locknut. Hold throttle closed and depress plunger. Clearance between throttle lever and plunger should be as listed. To adjust, turn dashpot in its bracket as required.

⑥—Open throttle plates halfway. Hold choke plate closed by means of choke housing shaft. Clearance between cast stop on back of choke housing and edge of fast idle cam should be as listed. To adjust, loosen bellcrank lever screw and turn lever as required to obtain correct clearance.

⑦—With choke plate fully closed, adjust bellcrank lever so that fast idle stop screw seats on next to highest step on fast idle cam.

⑧—Hold secondary throttle plates closed. Turn secondary throttle shaft lever out until the plates stick in throttle bores and there is the clearance listed between screw and throttle lever. Then turn screw in one full turn.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

A clutch pedal adjustment should be made whenever the clutch does not disengage or engage properly, or when new clutch parts are installed. Both the total travel and the free travel of the pedal should be adjusted.

Measure the total travel of the pedal which should be as follows:

Ford 1953-58	6 3/8" to 6 5/8"
Ford 1959-62	6 5/8" to 6 7/8"
T-Bird 1955-58	6 7/8" to 7 1/8"
T-Bird 1959-60	6 5/8" to 6 7/8"
Edsel 1958	6 3/8" to 6 5/8"
Edsel 1959-60	6 5/8" to 6 7/8"

If the correct dimension does not obtain move the clutch pedal bumper and bracket up or down until the travel is within correct limits. Adjust the assist spring link to give the spring the proper length as follows:

Edsel 1958-60	10 3/32"
Ford 1953-58	6 5/8"
Ford 1959-60	9 7/8"
Ford 1961-62	10"
T-Bird 1955-58	6 13/16"
T-Bird 1959-60	9 7/8"

After the correct total travel has been established, check the pedal free travel. Depress the clutch pedal by hand, then measure the distance the clutch pedal travels before the clutch begins to disengage. The free travel should be a minimum of one inch.

If an adjustment is necessary, loosen the lock nut on the clutch pedal release rod and turn the adjusting nut. When the adjusting nut is turned clockwise, free travel is increased, and vice versa. Tighten lock nut after adjustment has been made.

Service Note

The centrifugal weights in the clutch at high speed will move the release levers closer to the release bearing and reduce the pedal free travel by as much as 3/4". Therefore, it is recommended that the pedal free travel be checked while the engine is running at approximately 3000 rpm. This check can be made while the car is standing and transmission is in neutral. The free pedal travel under these conditions must be at least 1/2". Readjust if necessary to obtain at least 1/2" free pedal travel with engine running at approximately 3000 rpm.

CLUTCH SERVICE

Replace, 1957-62

1. Remove transmission as outlined further on.
2. Remove flywheel housing cover.
3. Remove release lever retracting spring and slide release bearing and hub off release lever.
4. If same pressure plate and cover assembly is to be reinstalled, mark cover and flywheel so that pressure plate can be installed in the same position.
5. Loosen clutch cover-to-flywheel bolts evenly to release the pressure plate spring tension.
6. Remove clutch and disc through opening in bottom of flywheel housing.
7. Reverse the foregoing procedure to install the clutch. Then adjust the free pedal travel as outlined previously.

Replace, 1955-56

Remove the transmission as outlined

Fig. 1 Synchromesh transmission without overdrive on 1958-60 Ford with 332 and 352 engines, 1956-60 Thunderbird and 1958 Edsel. Also used on 1958 and 1960 Edsel with overdrive.

further on. Slide the clutch release bearing and hub assembly off the end of the clutch release lever. Disconnect the clutch pedal release rod from the release lever assembly.

On 1955-56 models, remove the clutch release equalizer bar bracket from the flywheel housing and the equalizer bar. Remove the split bronze bushing from the bracket.

On all models, remove the flywheel housing. Prick-punch the flywheel and clutch cover so that at assembly these parts may be installed in their original position. Loosen the clutch-to-flywheel attaching screws a turn or two at a time until clutch pressure spring load is relieved. Then remove the screws and take the clutch from the flywheel.

Reverse the foregoing procedure to install the clutch. Then adjust the free pedal travel as outlined previously.

TRANSMISSION, REPLACE

1955-56 Ford

Drain the transmission. Disconnect gearshift linkage at the transmission. Remove speedometer cable and gear. Remove propeller shaft. Unfasten the transmission extension from the engine rear support. Place a jack under the engine to relieve its weight, then remove the frame crossmember and engine rear support.

Unfasten the transmission from the clutch housing. Install two guide pins in the upper holes. Slide the transmission to the rear until the main drive gear clears the clutch housing. Then lower the transmission and pull forward to remove it from the vehicle.

When removing transmissions equipped with overdrive, be sure first to disconnect the overdrive control cable and solenoid and governor wires.

1955-56 Thunderbird

Drain the transmission. Disconnect gear shift linkage at transmission. Remove speedometer cable and gear. Remove drive shaft. Remove cover from bottom of clutch housing and remove starter from clutch housing.

Disconnect clutch pedal linkage from clutch release lever.

Raise rear of engine slightly, then disconnect the engine rear mount and remove frame cross member. Place a jack under the transmission and unfasten the transmission from the clutch housing. Move the transmission toward the rear of the car so that the clutch parts can be removed from the clutch housing. After removing the clutch parts and flywheel housing, the transmission may be removed.

1957-59 Ford & Edsel

1. Raise car and disconnect drive shaft at rear universal joint flange.
2. Slide drive shaft off transmission output shaft.
3. Remove speedometer cable and gear.
4. Disconnect gearshift rods at transmission.
5. Unfasten engine rear support from transmission extension housing.
6. Disconnect parking brake adjusting rod from equalizer bracket.
7. Raise rear of engine to relieve weight on frame crossmember, then remove crossmember.
8. Lower engine and transmission for

Fig. 2 Synchromesh transmission without overdrive. Ford 1961-62, Ford 1955-57, Ford 1958-62 Six and V8-292 engines, Thunderbird 1955-57 with V8-292 engine. Also used on 1959-60 Edsel, without overdrive. Important: The overdrive transmission used with these models has the shift fork groove on the low and reverse mainshaft gear facing the front. Also there is no removable side cover, which necessitates removing the gears through the top of the transmission after the top cover is removed

clearance, then unfasten transmission from flywheel housing.

9. Install guide pins in the two lower transmission bolt holes.
10. Move transmission back and out of chassis.
11. Reverse foregoing procedure to install transmission.

1957 Thunderbird

1. Raise car and disconnect drive shaft at rear universal joint flange.
2. Slide drive shaft off transmission output shaft.
3. Remove speedometer cable and gear.
4. Disconnect gearshift linkage at transmission.
5. Unfasten engine rear support from extension housing.
6. Raise rear of engine and remove rear support.
7. Lower engine and remove bolts from transmission to flywheel housing.
8. Move transmission toward rear so that clutch pressure plate and cover can be removed.
9. Remove cover from bottom of flywheel housing.
10. Remove starter.
11. Disconnect clutch linkage at release lever, then remove release bearing and hub and clutch assembly.
12. Unfasten flywheel housing from engine block. Turn flywheel housing upside down and remove it from car.
13. Transmission can now be removed from car.
14. Reverse foregoing procedure to install transmission and clutch.

1958-60 Thunderbird

1. Disconnect drive shaft at rear U-joint.
2. Disconnect parking brake adjusting rod and parking brake cables from equalizer.
3. Remove exhaust pipes.
4. Remove two bolts that secure transmission to engine rear support.
5. Jack up transmission enough to take weight off crossmember.
6. Remove crossmember.
7. Disconnect speedometer cable bracket and cable at transmission.
8. Remove gearshift rods from transmission levers.
9. Unfasten transmission from clutch housing and remove.

1960-62 Ford & Edsel

1. Remove drive shaft.
2. Disconnect speedometer cable.
3. Disconnect gearshift rods from transmission levers.
4. Disconnect parking brake cable and support engine with a jack.
5. Unfasten extension housing from rear engine support.
6. Raise rear end of engine and remove engine rear support and frame crossmember as a unit.
7. Support transmission with a jack. Then unfasten transmission from clutch housing and install guide pins in the two lower holes.
8. Move transmission and jack rearward until input shaft clears clutch housing. If necessary, lower engine enough to get clearance for transmission removal. *Do not depress clutch pedal while transmission is removed.*
9. Reverse removal procedure to install transmission.

TRANSMISSION REPAIRS

The following describes the procedure for units without overdrive. For detailed service on the overdrive, consult the *Overdrive* chapter. To disassemble the transmission, see Figs. 1 and 2 and proceed as follows:

1. Remove gearshift housing.
2. Drive out the pin that retains the countershaft and idler gear shaft to the transmission case.
3. Unfasten the extension housing and twist it ¼ turn counterclockwise to permit removal of countershaft.
4. Drive countershaft out the rear of case, using a cluster gear roller retainer shaft tool or a spare countershaft cut to the length of the cluster gear. Leave cluster gear and dummy shaft in case until after main drive gear and mainshaft have been removed. Remove extension and mainshaft assembly from case.
5. Drive reverse idler shaft out of case and lift out reverse idler gear.
6. Unfasten and remove main drive

Fig. 6 Throttle linkage. 1955-56 Ford Six

Fig. 7 Throttle linkage. 1955-56 Ford V8 with two-barrel carburetor

gear bearing retainer.

7. Tap main drive gear out through front of case.
8. To disassemble mainshaft, remove snap ring that holds it to the extension housing. Tap mainshaft out of extension. Remove snap ring from in front of synchronizer and strip mainshaft of all parts.
9. After cleaning and inspecting parts, reassemble transmission by reversing the order of the foregoing procedure.

STD. TRANS. SHIFT LINKAGE, ADJUST

The gearshift rods are adjusted so that with the transmission gears in neutral, the two levers on the steering column are in line with each other. In this position, the shift lever can be moved up or down in neutral without binding.

AUTOMATIC TRANS. LINKAGE MANUAL LINKAGE

1955-57 Ford

1. With engine shut off, disconnect upper end of manual shift rod from selector lever.
2. Position selector lever so that indicator is down against stop in DR position.
3. Place transmission manual lever in DR detent (second from bottom).
4. Rotate manual shift rod clevis to obtain shortest rod length that will permit clevis pin to enter grommet in selector lever.
5. Turn clevis two additional turns counterclockwise and install clevis pin.
6. Lock clevis with lock nut.
7. Check pointer alignment for all positions of selector lever.

1955-57 Thunderbird

1. Disconnect manual shift rod from selector lever.
2. Position selector so that indicator at quadrant is against stop in DR position.
3. Position transmission manual lever in DR position (second from bottom).
4. Adjust length of manual shift rod by turning clevis lock nuts until clevis pin enters selector lever.
5. Turn clevis lock nuts one turn counterclockwise, then install clevis pin.
6. Lock clevis with lock nuts.
7. Check pointer alignment for all positions of selector lever.

1958 Ford

1. Disconnect upper end of manual shift rod and clevis from shift selector lever.
2. Position selector lever so that pointer is down against the steering column stop in the DR (Fordomatic) or D1 (Cruise-O-Matic) position.
3. Shift the manual lever on the transmission to the second detent from the bottom.
4. Rotate the clevis on the manual shift rod until the clevis pin can easily be inserted in the lever insulator.
5. Lock the clevis in place and connect the rod and clevis to the selector lever.
6. Check the pointer alignment for all positions of the selector lever.

1958-60 Thunderbird

1. With engine stopped, disconnect upper end of manual shift rod and clevis from shift selector lever.
2. Position selector lever so that pointer is down against the steering column stop in the D1 position.
3. Shift manual lever on transmission to the second position from bottom (D1 detent).
4. Rotate clevis on manual shift rod until it can easily be installed on the selector lever pin.

1959-62 Manual Controlled Two Speed Trans.

1. With engine stopped, loosen clamp at shift lever so that shift rod is free to slide in clamp.
2. Position selector lever in D position against steering column stop.
3. Shift manual lever at transmission into D detent position (second from rear).
4. Tighten clamp on shift rod.
5. Check pointer alignment for all selector lever positions.

1959-62 Three-Speed Trans.

1. With engine stopped, loosen clamp at shift lever so that shift rod is free to slide in clamp.
2. Position selector lever in D1 position.
3. Shift manual lever at transmission into second position from rear (D1 detent).
4. Tighten clamp on shift rod.

THROTTLE LINKAGE, ADJUST

1955-56 Six

1. Remove clevis pin from upper end of throttle control rod, Fig. 6.
2. Pull upward firmly but gently on throttle control rod to hold transmission lever against its internal stop.
3. Rotate throttle rod clevis until clevis pin enters clevis and accelerator shaft.
4. Lengthen throttle control rod by ro-

Fig. 8 Throttle linkage. 1955 Thunderbird

Fig. 9 Throttle linkage. 1955 Ford Special V8 with four-barrel carburetor

tating clevis 3 turns counterclockwise.

5. Assemble throttle control rod to accelerator shaft.
6. Check throttle linkage and relieve any binding conditions.
7. Road test car. And if band or clutch slippage is evident, increase rod length to 3½ turns but do not exceed 4 turns of the clevis.
8. If band or clutch slippage is not eliminated after 4 turns of the clevis, refer to *Oil Pressure Check* in *Fordomatic Chapter*.
9. Check transmission for kickdown action. If there is no kickdown, disconnect accelerator connecting link from accelerator cross shaft lever. Then adjust accelerator pedal height by turning threaded trunnion on accelerator connecting link until top surface of accelerator pedal is $4\frac{9}{16}$" from floor pan.

1955-56 Ford V8 (2-Bar. Carb.)

1. Disconnect throttle control rod from accelerator assembly, Fig. 7.
2. Insert a ¼" drill rod through holes in "Point A".
3. Adjust length of carburetor connecting link to close the carburetor against its stop.
4. Adjust accelerator assembly connecting link to obtain a pedal height of $3\frac{11}{16}$".
5. Remove ¼" rod and check the alignment at "A". The pin must re-enter freely.
6. With ¼" rod removed, adjust throttle control rod. Pull upward gently but firmly on the rod to hold the transmission against its internal stop.
7. Rotate clevis until its pin freely fits on accelerator assembly lever.
8. Then lengthen throttle control rod by rotating clevis 3 turns counterclockwise.
9. Assemble throttle control rod to accelerator assembly lever, and tighten clevis lock nut.
10. Check throttle linkage and relieve any binding condition.
11. Road test car. If band or clutch slippage is evident, increase length of throttle control rod to 3½ turns but do not exceed 4 turns of clevis.
12. If band or clutch slippage is evident after 4 turns of the clevis, check oil pressure as directed in the *Fordomatic Chapter*.

1955 Thunderbird

1. Disconnect throttle control rod from transmission control-to-accelerator assembly, Fig. 8.
2. Insert a ¼" drill rod at point "A".
3. Adjust length of carburetor connecting link to close carburetor against its stop.
4. Adjust accelerator assembly connecting link to obtain a pedal height of 4¼".
5. Remove ¼" rod and check alignment at point "A". Pin must re-enter holes freely.
6. With ¼" rod removed, pull upward gently but firmly on the rod to hold transmission lever against its internal stop
7. Rotate clevis until its pin fits freely.
8. Then lenghten throttle control rod by rotating clevis 3 turns counterclockwise. Hold clevis in alignment and tighten lock nut.
9. Road test car. And if band or clutch slippage is evident, increase length of rod to 3½ turns (not over 4) of the clevis.
10. If band or clutch slippage is not eliminated at 4 turns of clevis, check oil pressure as outlined in the *Fordomatic Chapter*.

1955 Ford Special V8 With 4-Barrel Carb.

1. Disconnect throttle rod from accelerator assembly, Fig. 9.
2. Insert ¼" drill rod through holes in accelerator assembly and bracket.
3. Adjust length of carburetor connecting link to close carburetor against its stop.
4. Adjust accelerator assembly connecting link to obtain a pedal height of $3\frac{9}{16}$".
5. Remove ¼" rod and check alignment; rod must re-enter freely.

Fig. 10 Throttle linkage. 1956 Ford V8 with four-barrel carburetor

Fig. 11 Throttle linkage. 1956 Thunderbird

Fig. 12 Throttle linkage. 1957-58 six cylinder

Fig. 13 Throttle linkage. 1957-58 Ford V8 with two barrel carburetor

6. With ¼" rod removed, pull upward gently but firmly on the rod to hold transmission lever against its internal stop.
7. Rotate clevis until its pin fits freely in accelerator assembly lever.
8. Then lengthen throttle control rod by rotating clevis 3 turns counterclockwise.
9. Assemble throttle rod to accelerator assembly lever with clevis pin.
10. Hold clevis in alignment and tighten lock nut.
11. Check throttle linkage and relieve any binding condition.
12. Road test car. And if band or clutch slippage is evident, increase length of throttle rod to 3½ turns (not over 4) of the clevis.
13. If band or clutch slippage is not eliminated at 4 turns of clevis, check oil pressure as outlined in *Fordomatic Chapter*.

1956 Ford V8 With 4-Barrel Carburetor

1. Disconnect throttle rod from accelerator assembly, Fig. 10.
2. Insert a ¼" drill rod through holes at point "A".
3. Adjust length of carburetor connecting link to close carburetor against its stop.
4. Adjust accelerator assembly connecting link to obtain a pedal height of $3\frac{9}{16}$".
5. Remove ¼" rod and check for alignment at "A". Pin must reenter freely.
6. Remove drill rod and adjust throttle control rod. Pull upward gently but firmly on rod to hold transmission lever against its normal stop.
7. Rotate clevis until it freely fits pin on accelerator lever.
8. Lengthen throttle control rod by rotating clevis three turns counterclockwise.
9. Assemble throttle rod to accelerator lever. Hold clevis in alignment to prevent binding and tighten lock nut.

Fig. 14 Throttle linkage. 1957-58 with four barrel carburetor

Fig. 15 Throttle linkage. Edsel 1958 Corsair and Citation

10. Check throttle linkage and relieve any binding condition.
11. Road test car. If band or clutch slippage is evident, increase length of throttle rod to 3½ turns but not over four turns of clevis. If band or clutch slippage is still not eliminated, make an oil pressure check.

1956 Thunderbird

Fig. 11 illustrates the linkage used on 1956 Thunderbird. The adjustment procedures are the same as the other 8-cylinder engines with 4-barrel carburetor except for pedal height, which should be 4¼".

1957-58 Six-Cylinder

1. Remove clevis from upper end of throttle control rod. Pull throttle control rod upward to hold throttle lever against main control stop.
2. Turn clevis until its pin will enter hole in throttle lever. Then lengthen rod 2½ turns.
3. Connect throttle rod to accelerator shaft and secure it with cotter pin temporarily.
4. Adjust accelerator pedal height by turning threaded trunnion on accelerator connecting link until the point where linkage connects to accelerator pedal is 3⅛" from floor mat, Fig. 12.

1957-58 V8 Ford & T-Bird

1. Referring to Figs. 13 and 14, disconnect throttle rod from accelerator.
2. Insert a ¼" drill rod through gauging holes. Adjust length of carburetor connecting link so that carburetor lever is held against its hot idle stop.

Fig. 18 Cruiseomatic throttle linkage. 1961-62

3. Adjust accelerator connecting link to obtain a pedal height of 3⅛" (4½" on 1958 T-Bird).
4. Remove drill rod and check alignment of holes.

Fig. 16 Throttle linkage. Edsel 1958 Ranger, Pacer and Wagons

5. Pull upward gently but firmly on throttle control rod to hold transmission lever against its internal stop.
6. Rotate clevis until it freely fits pin on accelerator lever. Then lengthen throttle control rod by rotating clevis 3 turns counterclockwise.
7. Connect throttle rod to lever.

Edsel Push Buttons, 1958

1. Turn on ignition switch and depress N button. Then turn ignition off.
2. Disconnect selector motor control rod from manual lever on transmission, Figs. 15 and 16.
3. Move manual lever on transmission to the rear or front until lever contacts the stop. Then move lever to the center of its travel (3 detents).
4. Loosen selector motor control rod lock nut and turn clevis until clevis pin can be inserted freely through clevis and manual lever on transmission. Then tighten lock nut.

1959-61 Ford & Edsel Six Manual Control Type

1. With engine stopped and carburetor at its hot idle position, disconnect turnbuckle or clevis at upper end of throttle control rod, Fig. 17 top view. Pull throttle control rod upward to hold throttle lever against stop inside transmission.
2. Turn throttle rod clevis or turnbuckle until pin enters hole in lever.

Then lengthen throttle rod 3½ turns and secure adjustment.

3. Adjust accelerator pedal height by turning threaded trunnion on accelerator connecting link until pedal is 3½″ from floor mat (dimension "C", Fig. 17 top view).
4. The foregoing is a preliminary adjustment. Final adjustment must be made by the pressure method as outlined in the automatic transmission chapter.

1961 V8 With Fordomatic and 1959-60 V8 Ford, T-Bird, Edsel

Manual Control Type

1. With engine stopped, disconnect throttle control rod and carburetor connecting link from accelerator assembly, Fig. 17 (center and bottom views).
2. Insert a ¼″ gauge pin through gauging holes at "A", Fig. 17.
3. Lift carburetor connecting link to its normal operating position. Maintain forward pressure on it so that carburetor throttle lever is held solidly against idle adjusting screw. Then adjust length of link so that threaded sleeve can be freely fitted into accelerator lever. From this position, rotate sleeve one full turn to lengthen the link. Remove ¼″ gauge pin and connect link to lever.
4. Check alignment of gauge pin holes. Open throttle and permit throttle linkage retracting spring to return linkage to its hot idle position. The pin must now enter freely; if not, readjust carburetor connecting link to obtain a free fit of gauge pin.
5. Remove gauge pin and adjust throttle control rod. Pull upward gently but firmly on rod to hold transmission lever against its internal stop.
6. Rotate turnbuckle or clevis until pin freely fits accelerator lever. Lengthen throttle control rod by 3½ turns (4½ on T-Bird).
7. Connect throttle control rod to accelerator lever.
8. Adjust connecting link to obtain a pedal height of 3½″ (dimension C, Fig. 17).
9. The foregoing is a preliminary adjustment. Final adjustment must be made by the pressure method as outlined in the automatic transmission chapter.

Fig. 17 Manually-controlled throttle linkage. Early 1961 two-speed transmission

1961-62 Thunderbird

Adjust accelerator pedal height to 3$\frac{11}{16}$″ by turning carburetor connecting link in or out. Then position speed nut on downshift lever-to-carburetor rod 1¼″ from front face of bushing in downshift lever.

1961-62 Ford Cruiseomatic

1. With engine stopped, disconnect carburetor connecting link from accelerator assembly. Insert ¼″ gauge pin through gauge holes at "A", Fig. 18.
2. Maintain forward pressure on carburetor connecting link so that carburetor throttle lever is held solidly against hot idle adjusting screw. Then adjust carburetor link so that the sleeve can be freely fitted into the accelerator lever. From this position, rotate sleeve one full turn counterclockwise to lengthen link. Remove gauge pin and connect link to accelerator lever.
3. Adjust carburetor connecting link to obtain a pedal height of 3$\frac{11}{16}$″ as indicated at dimension "C".

VACUUM-CONTROLLED THROTTLE LINKAGE

Late 1961 & 1962 Two-Speed Trans.

V8-292 and 352 Engines—Referring to Fig. 19, apply parking brake and place selector lever in "N". Then adjust as follows:

1. With engine at normal operating temperature, adjust idle speed to 485 rpm.
2. With throttle in hot idle position, bottom dashpot plunger and adjust dashpot so there is $\frac{5}{64}$″ clearance be-

Fig. 19 Vacuum-controlled throttle linkage. Late 1961 and 1962 Fordomatic

tween plunger and throttle shaft lever.

3. With engine stopped, disconnect carburetor connecting link from accelerator assembly.
4. Insert a ¼″ drill rod through gauging holes shown at "A", Fig. 19. Hold carburetor connecting link forward and adjust sleeve until link assembly fits freely in accelerator assembly. Then rotate sleeve counterclockwise one full turn. Remove drill rod.
5. Measure accelerator pedal height as indicated in dimension "C", Fig. 19. If height is not 3¾″, turn threaded trunnion on accelerator pedal link until correct height is obtained.

6-223 Engine:

1. Measure accelerator pedal height as shown in dimension "C", Fig. 19 (top view). If not 3¾″, turn threaded trunnion on accelerator connecting link until correct height is obtained.
2. Disconnect downshift control rod from bellcrank.
3. Block accelerator pedal to floor.
4. Push downshift control rod down to the limit of its travel. Then adjust sleeve on rod until end of rod enters bellcrank freely. Connect linkage and tighten lock nut.

TRANS. & CONV. REPLACE

Two Speed Units

1. Remove cover from bottom of converter housing.
2. Drain transmission and converter.
3. Remove drive shaft.
4. Disconnect linkage, speedometer cable and oil cooler lines at transmission.
5. Disconnect oil filler tube.
6. On 1961 models, disconnect pressure test line from transmission.
7. Remove starter motor.
8. Disconnect parking brake cable.
9. Remove engine rear support bolts.
10. Support transmission with jack and remove crossmember.
11. Unfasten converter from flywheel and converter housing from engine.
12. Secure converter to transmission so it will not fall out when transmission is separated from engine.
13. Work transmission off engine block dowel pins and toward rear until converter pilot clears crankshaft.
14. Lower transmission from car.
15. Reverse foregoing procedure to install the transmission. Then fill transmission with fluid and adjust control linkage as outlined previously.

1955-57 Thunderbird & All Convertibles

The frame construction of these models will not permit the transmission to be moved rearward far enough to clear the turbine shaft from the converter; therefore, the transmission and converter must be removed as a unit. The general procedure is as follows:

1. Drain transmission and converter.
2. Remove fluid filler tube.
3. On 1961 models, disconnect vacuum hose from vacuum diaphragm unit at transmission.
4. Remove flywheel-to-converter nuts. Install converter housing front plate to hold converter in place when transmission is removed.
5. Remove starter motor.
6. Disconnect oil cooler lines from transmission. Remove transmission vent tube (if equipped).
7. Disconnect linkage and speedometer cable from transmission.
8. Remove drive shaft.
9. On cars with single exhaust system it may be necessary to loosen and drop the exhaust to allow converter to clear exhaust pipe.
10. Remove engine support-to-transmission bolts. Support transmission with a jack and remove crossmember. Support rear of engine.
11. Unfasten converter housing from engine and move transmission assembly to the rear and down to remove it from the car.
12. Reverse removal procedure to install the transmission. Then fill with fluid and adjust controls as outlined previously.

TRANS. LESS CONV. REPLACE

Three-Speed Units Except Convertibles & 1955-57 T-Bird

1. On 1961-62 models, disconnect hose from vacuum diaphragm unit at transmission.
2. Disconnect fluid tube and drain fluid.
3. Remove drive shaft.
4. Disconnect oil cooler lines.
5. Remove vent tube (if equipped).
6. Disconnect linkage and speedometer cable at transmission.
7. Remove engine rear support-to-transmission bolts. Support transmission with a jack and remove crossmember.
8. Support engine and remove transmission-to-converter housing bolts.
9. Tilt rear of transmission upward and move assembly toward rear until clear of turbine shaft. Then lower and remove assembly from car.
10. Reverse removal procedure to install the transmission. Fill with fluid and adjust controls as outlined previously.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

1957-62 REAR AXLE

This rear axle, Fig. 1, is a banjo-housing hypoid in which the drive pinion is mounted below the centerline of the ring gear. The drive pinion is straddle-mounted in that two opposed tapered roller bearings support the pinion shaft at the front of the pinion gear and a straight roller bearing supports the pinion shaft at the rear of the pinion gear.

The pinion shaft and gear are assembled in the pinion retainer which is bolted to the carrier housing. Two carrier and differential cases are used to accommodate two bearing sizes.

Axle Shaft, Remove

Take off wheel and unfasten brake drum from axle shaft flange. Through hole provided in flange, remove nuts that secure brake support plate to axle housing. Then with suitable puller pull shaft out of housing. Use care not to dislodge the brake support plate or damage the oil seal in the housing. Install one nut to hold brake plate in position.

Axle Shaft Bearing, Replace

Axle shaft bearings should be removed only when necessary to install a new bearing. A bearing once removed should be discarded.

To replace a bearing, loosen axle shaft bearing retainer ring and remove retainer. The bearing may be removed with a bearing puller, after which remove retainer plate.

To install, place retainer plate on shaft. Press bearing up against shoulder on shaft. Install bearing retainer ring and press it firmly against bearing. Before installing shaft, examine oil seal and replace if necessary.

Oil Seal, Replace

Before installing a new oil seal it should be soaked in oil for at least 30 minutes to make it soft and pliable. When installing the seal, use a suitable seal

Fig. 1 Exploded view of 1957-62 rear axle (4 pinion differential also used)

Fig. 2 1955-56 passenger car rear axle assembly

driver, driving the seal into the axle housing and tight against the shoulder. When installed, check outer diameter of seal for tightness in housing to avoid possible leaks.

Axle Shaft, Install

Remove temporary nut holding brake plate, and lubricate bearing bore in housing. Clean brake plate surface and install new gaskets between retainer plate and brake plate. Slide axle shaft into housing, using care not to damage oil seal. Push shaft in until its bearing is tight against shoulder in housing. Tighten axle shaft nuts to a torque of 30-35 ft. lbs. and install brake drum and wheel.

Rear Axle, Remove

It is not necessary to remove the entire rear axle assembly to service the differential carrier assembly. After removing propeller shaft and axle shafts, unfasten the differential carrier from the axle housing and remove carrier from housing.

Rear Axle Repairs

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, are given in the *Rear Axle Chapter*.

The following service procedure is significant for this type axle.

Disassemble Carrier

1. Mark one differential bearing cap and bearing support to ensure proper assembly. Remove adjusting nut locks, bearing caps and adjusting nuts. Lift differential out of carrier.
2. Remove drive gear from differential case.
3. Drive out differential pinion shaft retainer and separate the differential pinion shaft and remove gears and thrust washers.
4. Remove drive pinion retainer from carrier. Remove O-ring from retainer.
5. Remove pinion locating shim. Measure shim thickness with micrometer.
6. If the drive pinion pilot bearing is to be replaced, drive the pilot end and bearing retainer out at the same time. When installing, drive the bearing in until it bottoms. Install a new retainer with the concave side up.
7. Mount the drive pinion retainer assembly in a holding fixture and remove pinion shaft nut and flat washer. Then remove universal joint flange, oil seal and slinger.
8. Remove pinion retainer from fixture and place a protective sleeve or hose on the pinion pilot bearing surface. Then press the pinion shaft out of front bearing cone and remove spacer.
9. Remove pinion rear bearing cone.
10. Do not remove pinion bearing cups from retainer unless they are worn

Drive shaft and universal joints

or damaged. The flange and pilot are machined by locating on these cups after they are installed in the bores. If new cups are to be installed, make sure they are seated in the retainer by trying to insert a .0015″ feeler gauge between cup and bottom of bore.

Assemble Carrier

Differential Case—Place a side gear and thrust washer in the differential case bore. *Lubricate all parts liberally with axle lubricant during assembly.* With a soft-faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear. Place the second pinion and thrust washer in position. Drive the pinion shaft into place. Be careful to line up pinion shaft retainer holes. Place second side gear and thrust washer in position and install differential case cover. Install retainer. A pinion or axle shaft spline can be inserted in side gear spline to check for free rotation of differential gears.

Insert two $\frac{7}{16}$″ x 2″ bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning the drive gear bolt holes. Press or tap the drive gear into position. Install and tighten the drive gear bolts evenly and alternately across the gear to 60-65 lb. ft. torque.

If the differential bearings have been removed, use a suitable press to install them.

Assemble Pinion

Pinion and Retainer—Install the pinion rear bearing cone on the pinion shaft and install a new spacer on the shaft. Place the bearing retainer on the pinion shaft, then install the front bearing cone. *As the bearing is pressed into position, rock the pinion retainer. Do not press the bearing on the shaft until all play is removed between retainer and bearings as the spacer may be compressed too much.*

Lubricate both bearings with axle lubricant. Place oil slinger in position. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the bearing retainer. New seals need not be soaked before installation. Install the universal joint flange. Place the flat washer over the pinion shaft and start the pinion shaft nut.

Hold the flange and tighten the pinion shaft nut until a torque required to turn the pinion is 8-12 *inch* lbs. with used bearings or 17-27 *inch* lbs. with new bearings. As the pinion shaft nut is tightened, rotate the pinion shaft frequently to allow the bearing to seat.

Pinion, Adjust

Shim Selection—Manufacturing tolerances in the pinion bore dimensions and in the best operating position of the gears make an adjustment shim necessary. This shim is placed between the pinion retainer and the carrier, Fig. 1. An increase in the thickness of the shim moves the pinion *away* from the drive gear. Manufacturing objectives are to make axles requiring a .0015″ shim and if a new assembly is being built, a .0015″ shim should be used for a tentative build-up. Shims are available in .010″ to .021″ thicknesses in steps of .001″.

Pinions and drive gears are marked, when matched, with the same number. Following the number on the pinion is a minus (—) or plus (+) followed by a number. If the pinion is marked "—1" it indicates that a shim .001″ thinner than a standard shim for this carrier is required. A minus number means the pinion should be moved closer to the drive gear and a thinner shim is required. A plus number means the pinion should be moved farther from the drive gear and a thicker shim is required. A pinion marked zero (0) is a standard pinion.

To select a shim, measure the original shim with a micrometer. Note the dimensional mark on the original pinion. Compare the mark on the original pinion with the mark on the new pinion to determine how the original shim should be modified.

For example, if the original shim is .015″ and the original pinion is marked "—1", the new pinion requires a +1 shim. Therefore, the new pinion requires a .002″ thicker shim, and a .017″ shim should be used. If the new pinion is marked the same as the old pinion, no shim change is required.

1955-56 REAR AXLE

Ford Pass. Car

Fig. 2 illustrates the rear axle assembly used on passenger cars only.

The splined universal joint flange is fastened to the pinion shaft with a nut which seats directly on the counterbore in the flange.

The drive pinion is mounted on taper roller bearings. Adjustment of the pinion along its axis is obtained by shims placed between the rear bearing outer race and a shoulder in the carrier. Preload of the two bearings is obtained by tightening the universal flange nut which compresses a spacer over the pinion shaft between the bearings. Both bearing outer races are pressed into the carrier, the rear race against pinion adjusting shims, the front race against the shoulder in the carrier. The rear bearing inner race is pressed onto the pinion shaft to a shoulder at the pinion end. The front bearing is a light press fit to a close sliding fit on the pinion shaft.

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

Pinion & Bearings, Replace

After removing the differential unit from the carrier, unscrew the pinion flange retaining nut and pull off the flange. Press the pinion out of the front bearing and through the rear end of the carrier. The rear bearing cone and bearing spacer will come out with the pinion. The bearings may then be removed and installed with suitable pulling equipment.

Reverse the operations to assemble and, after pressing on the flange, slip on the washer and nut. Tighten the nut until the bearings have a preload drag of 22 to 28 inch pounds of torque to rotate the pinion shaft.

To adjust the preload, draw up the nut with a torque wrench until the spacer starts to buckle. This adjustment must be made every time the flange nut is removed or loosened. If the adjustment is to be made with the differential in the carrier, the rear wheels must be jacked off the floor.

Drive Pinion Position

The drive pinion position usually does not require adjustment other than the bearing preload unless a new pinion bearing cup is installed. If a new rear bearing cup is installed, check the pinion position by using a micrometer depth gauge as outlined in the *Rear Axle* chapter. If the depth of the pinion measures more than 2.000″ (plus or minus .002″) it will be necessary to install shims in back of the pinion shaft rear bearing cup. Shims are available in .003, .005, .010, and .020″ thicknesses for this purpose.

Note—A new pinion bearing spacer is required when a new ring gear and pinion set is installed, when any part of either pinion bearing is changed, when a new carrier casting is used, or when pinion adjusting shim thickness is increased. When the same universal joint flange is removed and reinstalled (as when an oil seal is replaced) checking for pinion bearing preload with a torque wrench is not necessary if care is taken to tighten the nut exactly to its previous position. Should a new flange be required, a torque wrench reading should be taken before loosening the nut and the nut tightened to the same torque wrench reading.

Axle Shaft, Replace

The procedure for replacing an axle shaft, bearing and oil seal is the same as outlined for 1957 and later models.

1955-56 REAR AXLE

Ford Sta. Wagon and T-Bird

In this type axle, Fig. 3, the drive pinion is held in position by shoulders in the differential carrier, upon which the pinion bearing cups seat. The pinion position is maintained by shims located between the rear bearing and the rear shoulder in the differential carrier. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The shimmed type of differential bearing adjustment is employed. The procedure for making this adjustment, as well as the assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

The axle tubes are pressed into the differential carrier to form a one-piece housing. To overhaul the unit, therefore, the rear axle assembly must be removed from the chassis.

Pinion & Bearings, Replace

After removing the axle shafts and differential unit, unscrew the pinion flange retaining nut and pull off the flange. The pinion may then be removed from the carrier by driving it out of the front bearing with a brass drift and hammer. After the pinion is free of the front bearing, pull it out through the rear of the carrier.

Mount the pinion in a press and press the pinion shaft out of the bearing. When replacing the bearing select a suitable sleeve or length of pipe of the same diameter as the cone so the rollers or cage will not be damaged when being forced on the shaft.

Drive the front bearing cup and oil seal out of the forward end of the carrier. If the rear bearing cup is to be replaced or if the pinion setting is to be changed, remove the rear bearing cup.

To change the pinion setting, the shims behind the rear bearing cup should be measured with a micrometer. The necessary shims may then be removed or added to obtain the proper pinion setting as indicated when a pinion setting gauge is used (see *Rear Axle* Chapter). After the required shims have been added or subtracted, replace the rear bearing cup.

When making a pinion adjustment, the same thickness of pinion bearing adjusting shims should be added or removed at the rear bearing cup to retain the proper pinion bearing adjustment.

To install the pinion, support it under the head with a wood block while the pinion flange is reinstalled. The pinion oil seal should not be replaced until after the pinion setting has been checked.

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearing are tight, but still permit rotating the pinion by hand.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion may be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle* Chapter. If a correction is necessary, disassemble the pinion and, if it is to be moved toward the center of the axle, add shims between the rear bearing and rear shoulder in the carrier. If the pinion has to be moved away from the center of the axle, remove shims from this point.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle* Chapter. After satisfactory tooth contact has been established, remove the pinion flange to install the seal.

Axle Shaft, Replace

The procedure for replacing an axle shaft, bearing and oil seal is the same as outlined for 1957 and later models.

MASTER CYLINDER, REPLACE

1955-56

1. Disconnect wires at stop light switch and remove switch.
2. Disconnect brake line from master cylinder and depress brake pedal a few times to force out all fluid.
3. Remove eccentric bolt which attaches master cylinder push rod to brake pedal.
4. Remove master cylinder from dash panel.
5. Reverse removal procedure to install and bleed the brakes as outlined in the *Hydraulic Brakes* chapter.

1957-62 Ford, 1957 T-Bird, 1958 Edsel

1. Disconnect rubber boot from rear end of master cylinder in passenger compartment.
2. Disconnect brake line from master cylinder fitting. If stop light switch is attached to cylinder, disconnect wires from switch.
3. On 1957-59, force as much brake

Fig. 3 Integral housing rear axle. 1955-56 Thunderbird and Ford Station Wagon

fluid as possible from cylinder into a suitable container by pushing down brake pedal all the way several times.
4. Unfasten cylinder from dash panel and lift cylinder away from push rod and out of engine compartment. On 1960-62, remove rubber boot from push rod.

1958-60 Thunderbird

1. Disconnect stop light switch wires from switch. Remove brake bolt and two copper gaskets from master cylinder.
2. Force as much fluid as possible from cylinder into a suitable container by pushing down several times on the brake pedal.
3. Remove four nuts that attach cylinder to dash panel; then lift cylinder and boot away from push rod and out of engine compartment.

1959 Edsel

1. Working inside passenger compartment, remove eccentric bolt, bushings and lock nut which secure master cylinder push rod to brake pedal.
2. Working inside engine compartment, remove hollow nut attaching stop light switch and hydraulic line outlet fitting to master cylinder.
3. Unfasten and remove master cylinder from dash panel.

1960 Edsel

1. Working inside passenger compartment, remove the "C" washer and spring washer that secures the master cylinder push rod to the brake pedal. Remove push rod and bushing from pedal.
2. Remove hydraulic line outlet fitting from master cylinder.
3. Remove stop light switch.
4. Remove two capscrews which secure master cylinder to engine side of dash panel and remove cylinder.

POWER BRAKE UNIT, REPLACE

1962

1. Working inside care below instrument panel, disconnect booster push rod link from brake pedal by removing the horseshoe retaining clip and sliding push rod link off pin that is integral with pedal.
2. Open hood and disconnect wires from stop light switch at master cylinder.
3. Disconnect brake line at master cylinder outlet fitting.
4. Disconnect vacuum hose from booster unit. Also disconnect transmission throttle valve hose (if equipped).
5. Unfasten booster (4 bolts) from dash panel and slide push rod link out from engine side of dash panel.
6. Reverse removal procedure to install the booster. Then bleed the brake system.

1957-60 Ford (Bellows Type)

1. Disconnect vacuum hose at top of power unit.
2. Remove nut from valve-adjusting eccentric and take off flat washer, spring and bushing.
3. Remove valve-adjusting eccentric.
4. Remove nylon bushing from power unit valve housing.
5. Unfasten power unit from dash panel.

Installation

1. Pull brake pedal back toward car seat until master cylinder push rod comes out of master cylinder. Let push rod hang free.
2. Position power unit mounting bracket on dash panel. Be sure brake pedal trigger is in position against the air valve button before tightening attaching nuts and screws.
3. Install valve-adjusting eccentric and bumper through brake pedal, power lever and valve housing of power unit.
4. Slide eccentric bushing over eccentric and into valve housing.
5. Install eccentric spring with larger coils toward housing. Install washer and nut.
6. Tighten eccentric nut to the point that the eccentric bolt is firmly locked to power lever, but can still be turned for adjustment.
7. Attach vacuum hose and start engine.
8. Turn eccentric until unit chatters when pedal is depressed. Then turn eccentric until chatter disappears. Do not turn eccentric more than necessary or the unit "cut-in" will be excessively high. After adjustment, tighten eccentric nut. Check adjustment after nut is tightened.
9. Disconnect mounting bracket from dash.
10. Pull pedal and power unit back and insert master cylinder push rod in cylinder boot. Install nuts and screws that attach mounting bracket to dash panel.
11. Loosen push rod eccentric lock nut only enough to turn eccentric.
12. Rotate eccentric clockwise to its maximum travel. This will shorten push rod, permitting master cylinder piston to return to fully released position.
13. Rotate eccentric in a counterclockwise direction until master cylinder piston starts to resist movement of push rod. Hold eccentric and tighten lock nut.
14. Check master cylinder for bubbles or spurt at compensator port, which indicates push rod is properly adjusted.

1960-61 Ford (Piston Type)

1. Working inside the vehicle under the instrument panel, remove and discard the horseshoe-type retaining clip. Push the retaining bolt through the brake pedal and power brake push rod.
2. Open the hood. Disconnect wires from stop light switch at brake master cylinder. Remove brake line from master cylinder outlet fitting.
3. Remove vacuum hoses from power unit.
4. Unfasten and remove power brake unit from cowl panel.
5. Reverse above procedure to install the unit; then bleed the system.

1960-61 T-Bird (Piston Type)

1. Working inside of car under instrument panel, remove eccentric bolt lock nut and push eccentric bolt out through brake pedal and power brake push rod.
2. Open hood. Disconnect wires from stop light switch and remove brake bolt from master cylinder outlet.
3. Remove vacuum hoses from brake unit.
4. Unfasten and remove power unit from cowl panel.
5. Reverse above procedure to install; then bleed system.

1958-60 T-Bird (Bellows Type)

1. Remove master cylinder.
2. Remove headlamp beam selector switch and left cowl trim panel.
3. Remove hood control cable from bracket, and then remove bracket.
4. On cars with overdrive, remove overdrive control handle and bracket.
5. After detaching left vent-air register panel (6 screws and 3 bolts), lower parking brake handle, tilt panel outward at bottom and remove panel.
6. Disconnect vacuum hose at power unit. Detach and slide valve adjusting eccentric to the left until head of eccentric contacts brake pedal.
7. Detach power unit from its mounting bracket (2 bolts and 2 self-tapping screws) and remove power unit from trigger and out of car.

Installation

1. Position power unit mounting bracket on dash panel, being sure brake pedal trigger is positioned against air valve button to avoid damage to button. Fasten power unit in place.
2. Slide valve adjusting eccentric and bumper through brake pedal extension, power lever and valve housing.
3. Slide eccentric bushing (either end) over valve adjusting eccentric and into valve housing.
4. Install eccentric spring with larger coils toward housing. Install washer and nut.
5. Tighten valve adjusting eccentric nut to a point that the eccentric bolt is firmly locked to power lever but can still be turned for adjustment.
6. Attach vacuum hose.

Adjustments

Start engine. Turn valve adjusting eccentric until unit chatters when pedal is applied. Then turn eccentric until chatter disappears. *Do not turn eccentric more than necessary or the unit "cut-in" will be excessively high.* If a satisfactory adjustment cannot be obtained, the pedal trigger may be bent.

1958-60 Edsel

1. Working inside the front passenger compartment, disconnect the push rod from the brake pedal lever.
2. Working in the engine compartment, remove the hydraulic cylinder outlet connector bolt. *It is not necessary to remove the stop light switch, wires or brake line from the outlet fitting.*
3. Disconnect the two vacuum hoses from the vacuum inlet tubes attached to the side of the cylinder.
4. Remove the four screws that attach the power brake unit to the adapter on the dash panel, then remove the unit.
5. Installation is made in the reverse order of removal. When installed, fill and bleed the brake system.

1957 Thunderbird

To remove the unit, depress brake pedal several times to remove all vacuum from system. Disconnect hydraulic lines and vacuum hose at booster. Remove booster unit from mounting bracket.

Install the unit in the reverse order and bleed the air from the brake system.

1955-56

To remove the unit, depress the brake pedal several times to remove all vacuum from the system. Disconnect hydraulic lines and vacuum hose at the power unit. Disconnect the stop light switch wires at the switch. Remove the power unit from the mounting bracket.

Install the power unit on the mounting bracket. Connect the stop light switch wires. Bleed the brake system. Connect the vacuum hose and tighten the clamps securely. Connect the hydraulic lines.

Front End and Steering Section

CAMBER & CASTER, ADJUST

1961-62 Thunderbird

Camber—Adjust camber by removing or installing shims between pivot bracket of lower control arm and mounting bracket on underbody in engine compartment, Fig. 1.

Removal of shims will increase camber; installing shims will decrease camber. A $\frac{1}{16}$" shim change will change camber angle ⅓°.

Caster—Adjustment is made by repositioning strut on lower control arm as shown in Fig 1. Adjust caster by loosening rear retaining bolts and lift strut so that strut serrations will be free from serrations on lower arm.

Lengthen distance of "Dimension A", Fig. 1, to decrease caster and shorten distance to increase caster angle. Tighten rearward nuts that retain strut to lower control arm and recheck caster and camber.

1955-62 Ford & Edsel

To adjust caster, loosen the two bolts that secure the upper suspension arm shaft to the frame and insert shims between the shaft and frame. A $\frac{1}{16}$" shim at the front bolt will add a positive caster of ½ degree. A $\frac{1}{16}$" shim removed at the front bolt will produce a negative caster of ½ degree. Shims are available in thicknesses of $\frac{1}{32}$" and ⅛". When caster is correct, tighten bolts securely.

To adjust camber, insert or remove an equal number of shims from between the shaft and frame at both the front and rear bolts. Each $\frac{1}{16}$" of shim will change camber ¼ degree.

1958-60 Thunderbird

Camber and caster is adjusted in the same manner as outlined above for Ford except that the shims are located between the inner shaft of the suspension upper arm and the mounting bracket on the underbody in the engine compartment.

1955-57 Thunderbird

Camber and caster is adjusted in the same manner outlined for Ford except that the shims are located on the engine side of the bracket. Thus, when adjusting caster on these cars, the removal of shims at the front bolt will produce a positive caster. A shim added to the front bolt will produce a negative caster.

To adjust camber insert or remove an equal number of shims at both bolt positions.

Fig. 1 Caster and camber adjustments. 1961-62 Thunderbird

TOE-IN, ADJUST

Position the front wheels in their straight-ahead position. Then turn both tie rod adjusting sleeves an equal amount until the desired toe-in setting is obtained.

WHEEL BEARINGS, ADJUST

Pack the wheel bearings with the proper lubricant. Install the wheel, hub and drum as a unit. Tighten the spindle nut with a 12" wrench, while rotating the wheel back and forth, until there is a noticeable drag or bind. This assures that the bearing cones are properly seated. Then back off the spindle nut to line up to the nearest cotter pin hole which will allow the hub to rotate freely with no perceptible end play. Lock the spindle nut in this position with a cotter pin and install the grease cap and hub cap.

Remove the support stands and check the wheel alignment as previously outlined.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints as follows:

A method of checking the friction load on the upper joints by means of a torque wrench is provided. After separating the upper joint from the steering knuckle, the joint stud nut is installed and tightened on the stud. The stud is then turned in its socket with an inch-pound torque wrench. The torque should range from 20 to 35 inch pounds. If reading is below the minimum, replace the joint.

To check lower joint, jack up under the frame rather than under lower control arm to maintain the coil spring load on the lower joint. Then grasp the tire at the top and bottom and move it in and out. If movement at edge of tire exceeds ⅛", ball joint is worn and should be replaced.

FRONT END REPAIRS

1961-62 Thunderbird Ball Joints

1. Remove ball joint from arm. If ball joint is riveted to arm, drill a ⅛" pilot hole completely through each rivet. Then drill off the rivet head through the pilot hole with a ⅜" drill. Drive all rivets out of holes.
2. Clean end of arm and remove all burrs from hole edges. Check for cracks in metal at the holes and replace arm if cracked.
3. Install new ball joint, *using the special bolts, nuts and washers supplied with the ball joint. Do not attempt to rivet new ball joint to arm.*
4. Torque ball joint stud nuts to 60-80 ft. lbs. Lubricate ball joints and check caster and camber angles.

Shock Absorber

When installing, position the shock absorber and upper mounting plate in place and install mounting plate bolts and dash panel brace nuts. Lower car slightly with safety stands under lower control arm. This will raise upper arm enough to position lower shock absorber stud through hole at bottom of spring lower seat. Secure shock absorber to spring seat by installing insulator, washer and retaining nut.

Front Spring

1. With safety stand under lower control arm, remove wheel, shock absorber and upper control arm bumper and bracket.
2. Raise car slightly in order to lower upper control arm.
3. Insert a lock bar through top of spring and position bar on 7th coil from bottom and compress spring until top coils are drawn out of spring upper seat.
4. Remove 4 bolts attaching lower spring seat to upper arm and remove spring and lower seat as an assembly.
5. If a new spring is being installed, tape rubber insulator to upper end of spring in 3 places. Fasten spring seat to spring and install spring in reverse order of removal.

Fig. 3 Front suspension on Ford 1957-59, Edsel 1958 and T-Bird 1958-59. For 1960-62 Ford, 1960 T-Bird and 1959-60 Edsel, the upper control arm shaft bushings are the screw type

FRONT END REPAIRS

All 1955-60 & 1961-62 Ford

This suspension differs from other types in that wheel spindle is attached directly to the suspension arms by means of ball joints located at the outer ends of both arms. The conventional steering knuckle, knuckle support and kingpin is eliminated, Figs. 3 and 4.

The working parts of this type suspension are assembled directly to the vehicle frame and cannot be removed as an assembly. However, individual parts may be replaced as outlined below.

Shock Absorber

To remove a shock absorber, unfasten it from the frame at its upper end. Remove the two cap screws that retain the shock absorber mounting plate to the lower control arm and lower the shock absorber unit.

To install, reverse the removal procedure and tighten the two lower cap screws to 13-18 lbs. ft. torque.

Lower Arm & Spring, Remove

Raise the front of the car and place a support stand under each frame side rail to the rear of the lower control arm. Remove the hub cap and pry off the grease cap. Remove the nut from the wheel spindle and pull off the wheel assembly with hub and brake drum.

Remove the shock absorber as outlined above and detach the stabilizer (stabilitor) bar from the lower control arm.

Loosen the slotted nut which attaches the lower ball joint stud to the lower spindle boss one or two turns. Then with a brass bar and hammer, strike the lower spindle boss to pop the stud loose against its nut. Place a jack under the outer end of the lower arm and raise the jack until the upper arm rebound bumper is clear of the frame. The nut can then be removed and the spindle and brake assembly lifted off the ball joint stud and moved out of the way.

Fig. 4 Front suspension. Ford 1955-56 and T-Bird 1955-57

Lower the jack until the coil spring is free and can be removed. Note the rubber insulators at the upper and lower ends of the spring.

Unfasten the lower control arm from the frame and remove the arm. Inspect the bushings on the inner end of each arm leg and replace if defective.

When installing bushings, do not attempt to press them beyond the edge of the shoulder ribs as severe distortion will result, which will affect the operation of the suspension unit. Under no circumstances should only one bushing be replaced.

Ball Joint Service

Remove the cover and seal from the ball joint. Inspect the joint and replace if found defective. If the joint is still serviceable, *do not* wash it in solvent as it will be extremely difficult to lubricate it again. Do not hammer the ball joint bodies as binding will result. Inspect the metal seal parts for damage and replace if necessary. Replace the sponge rubber seal, making sure it is stuffed into the metal seal cup before pushing it down over the ball joint stud.

Lower Arm & Spring, Install

To install the lower control arm, secure the rearward leg to the frame crossmember tube, running the nut up finger tight. With the arm forced firmly against the tube, install enough shims to fill the space between the forward arm leg bushing and front crossmember. Then install the bolt and washers and run the nut up finger tight. With the arm in curb load position (approximately horizontal) with the outer end slightly lower than the inner, tighten the nuts to 80-100 lbs. ft. torque.

Place the coil spring with the rubber insulators in position on the lower control arm. Then with a jack under the lower arm, compress the coil spring. Care must be taken to see that the upper and lower ends of the spring are properly seated and the rubber insulators are in place. Guide the spindle boss over the ball joint stud. Install the nut and torque it to 100 lbs. ft. Continue to tighten until the cotter pin holes are lined up and install the cotter pin.

Remove the jack from under the arm and install the shock absorber. Secure the stabilizer bar to the lower suspension arm.

Upper Arm, Remove

Remove the shock absorber. Place a jack under the lower control arm spring seat and raise it until some of the tension has been removed from the upper bumper. Remove the wheel and tire assembly.

Wire the spindle to the frame to avoid possible damage to the brake hose from undue tension. Loosen the ball joint stud by backing the nut off one or two turns and striking the spindle boss. Remove the stud nut completely and then remove the two bolts that secure the inner shaft to the frame. Note the number of shims between the shaft and frame at each of the bolt locations. Then take off the upper control arm.

When installing bushings, be sure to use a spacer tool of the proper dimensions between the arm legs so that the arm will not be distorted or bent. When both bushings are in place, install the nut and washer on each end of the shaft and tighten finger tight. Position the shaft in the arm so that the shaft bolt holes are parallel with the arm. Then tighten the nuts from 80-100 lbs. ft. torque. Under no circumstances should only one bushing be replaced.

Note—The upper ball joint is serviced in exactly the same way as the lower.

Upper Arm, Install

Position the arm on the frame crossmember. Use the same number of shims that were originally used between the shaft and frame bracket. Secure the shaft to the bracket with the two bolts and torque the bolts to 75-90 lbs. ft. Place the ball joint stud in the spindle boss, install the nut and tighten it to 80 lbs. ft. minimum. Continue to tighten until the cotter pin holes are lined up and install a cotter pin.

Install the wheel and hub assembly and remove the jack from under the lower control arm. Finally, check the wheel alignment as previously outlined.

HORN SOUNDER

1961-62 Thunderbird

Unsnap hub cap from horn ring. Remove steering wheel nut and pull off steering wheel and horn ring.

1958-60 Thunderbird

To remove the horn ring, pull off the decorative cover at the center of the steering wheel and remove the wheel from the steering shaft. Remove the turn signal cancelling cam and ground contact ring. Removal of the three retaining screws then allows complete disassembly of the remaining parts.

1960-62 Ford

On 1960 Fairlane and all 1961-62 models, the horn button can be removed by pressing down evenly and turning the button counterclockwise until it lifts out. On the other models the horn ring is retained by two screws.

1960 Edsel

Remove steering wheel cap and horn ring by removing two screws under steering wheel.

1959 Edsel

Pry emblem cap out of steering wheel hub with screwdriver or knife blade.

1958 Edsel

The following applies to the horn ring and contact plate assembly used with the push button type steering column.

1. Unsnap the medallion from the center of the push button trim plate. Remove the two screws and lift off the trim plate.
2. Pull the push buttons off their pedestals.

Fig. 6 Conventional steering gear, 1955-57 Ford and T-Bird

3. Remove the three screws from inside the horn ring hub and lift off the horn ring.
4. Unscrew the three nuts that attach the horn contact plate and steering wheel to the wheel hub.
5. Lift off the horn contact plate assembly. *The horn wire in the push button switch and tube assembly is not replaceable. Therefore, should trouble occur in this assembly, replace the complete tube assembly.*

Installation

1. Install contact plate on the three steering wheel studs. Install and tighten the three nuts.
2. Secure horn ring to contact plate with three screws.
3. Press push buttons on their proper pedestals.
4. Install push button trim plate.
5. Snap medallion in slots in trim plate.

1955-59

The horn button can be removed by pressing down evenly and turning the button counterclockwise until it lifts out.

Thunderbird 1955-57

On Thunderbird the horn ring is removed by first removing the two screws at the back of the steering wheel.

STEERING WHEEL

Ford & T-Bird

After removing the horn button or emblem from the steering wheel as outlined above, take off the steering wheel nut and use a suitable puller to remove the wheel.

1960 Edsel

Remove steering wheel cap and horn ring by removing two screws from underside of steering wheel. Remove retaining nut and pull off steering wheel.

Conventional Type, 1958-59 Edsel

1. Use a small screwdriver or knife blade and pry the emblem button out of the steering wheel hub.
2. Remove the steering wheel retaining nut.
3. Place front wheels in straight-ahead position.
4. Then with a suitable puller, remove steering wheel.
5. When installing the steering wheel, make certain the front wheels are in the straight-ahead position.

Push Button Type, 1958 Edsel

1. Unsnap the medallion from the center of the push button trim plate.
2. Remove the two screws and lift off the trim plate.
3. Pull off the push buttons.
4. Remove the three screws and lift off the horn ring.
5. Remove three nuts and lift off plate and steering wheel from studs.
6. Install steering wheel by placing it over the three studs. Install contact plate and tighten nuts.
7. Install horn ring and retaining screws.
8. Press on push buttons and install trim plate and medallion.

STEERING GEAR, REPLACE

1955-56 Ford

To remove the steering wheel, disconnect the horn wire at the connector at the bottom of the gear housing. Remove the horn button or ring by pressing down and turning the button or ring counterclockwise. Pull the horn wire out of the steering gear shaft. Remove the nut and, with a suitable puller, remove the steering wheel.

To remove the steering gear, disconnect the steering column from the instrument panel. Disconnect the gearshift levers from the gearshift rods. Remove the capscrew from the bracket that secures the gearshift tube to the steering column tube and remove the bracket. Remove the gearshift tube pin and the gearshift levers.

Loosen the steering column clamp and pull the column tube off the steering gear shaft. Disconnect the steering arm from the linkage and use a puller to remove the steering arm from the steering gear. Unfasten the steering gear housing from the frame and take the gear out of the car. (It may be necessary to raise the car before the gear can be taken out.)

1955-57 Thunderbird

To remove the steering gear, disconnect the wires at the bottom of the steering gear housing. Loosen the lower steering column clamp, then remove the two screws from the upper steering column bracket.

Remove the horn ring from the steering wheel. Remove the upper steering column, upper steering shaft, and steering wheel as an assembly from the car.

Raise the front of the car. Remove the steering arm from the steering gear shaft. Unfasten the steering gear housing from the frame and remove the lower steering gear assembly from the car.

1957 Ford

On all cars except those with Fordomatic, the steering gear must be removed through the engine compartment. On cars with Fordomatic, remove the steering gear through the passenger compartment.

1. Remove steering wheel.
2. Disconnect turn signal wires under instrument panel.
3. Remove two screws that fasten

steering column bracket to instrument panel. On cars without Fordomatic, remove turn indicator lever and gearshift lever from steering column.
4. Pull rubber weather seal up on steering column, then fold floor mat back from steering column.
5. Remove retaining screws from cover plate on engine compartment wall. Disconnect speedometer cable from instrument panel and remove right-hand cover plate from cable.
6. Disconnect Fordomatic or gearshift rods from levers on steering column.
7. On Fordomatic cars, disconnect neutral switch wires at bottom of column.
8. On cars with cynchromesh transmission, remove clutch return spring bracket.
9. Remove sector shaft arm nut and use a suitable puller to remove arm from shaft. On cars with single exhaust system, muffler inlet pipe must be removed before removing sector shaft arm.
10. Unfasten steering gear from frame and remove from car.

Ford 1958-60 Six and V8-292 With Synchromesh Transmission

1. Remove steering wheel.
2. Disconnect turn indicator wires under instrument panel.
3. Unfasten steering column bracket from instrument panel.
4. Remove turn indicator lever and gearshift lever.
5. Pull rubber seal up on steering column and fold mat away from steering column.
6. Remove screws from steering column weather seal on engine compartment wall.
7. Disconnect speedometer cable from instrument panel, remove right-hand cover plate and feed cable through cover plate.
8. Disconnect clutch pedal release rod at clutch pedal and remove cover plate from rod.
9. Disconnect clutch return spring.
10. Disconnect gearshift linkage at steering column bracket.
11. Remove nut and pull pitman arm from steering shaft.
12. Unfasten steering gear from frame and remove gear through engine compartment.
13. Reverse removal procedure to install.

Ford 1958-60 V8-332 Conventional Drive and All Models with Automatic Transmission

1. Remove steering wheel.
2. Disconnect turn indicator wires under instrument panel.
3. On cars with automatic transmission, remove selector dial indicator cover and control selector indicator.
4. Unfasten steering column bracket from instrument panel.
5. Remove screws from steering column weather seal, disconnect speedometer cable at speedometer, remove steering column opening cover plates and route cable through weather seal.
6. Disconnect manual control linkage at steering gear.
7. On synchromesh transmission cars, disconnect clutch equalizer bar.
8. Disconnect neutral switch wires at bottom of steering column (if equipped).
9. Place front of car on safety stands.
10. Pull pitman arm off steering shaft.
11. Unfasten steering gear housing from frame and remove steering gear through inside of car.
12. Reverse removal procedure to install the gear.

1958-60 Thunderbird

1. Remove steering wheel.
2. Disconnect parking brake handle bracket and remove cowl side trim panel and left vent control handle.
3. Disconnect hood lock release cable bracket.
4. On cars with Cruise-O-Matic, remove starter neutral switch screws and move switch to one side.
5. Disconnect horn wire, and wiring assembly from steering column.
6. Unfasten and move instrument panel lower panel to one side.
7. Pull aside steering column cover plate insulation and disconnect parking brake bracket.
8. Remove steering column cover plate and parking brake handle.
9. Unfasten steering column from instrument panel.
10. On cars with conventional shift transmission, disconnect clutch linkage as necessary to provide clearance for steering gear removal through inside of car.
11. Disconnect shift lever(s) near steering column.
12. Pull off Pitman arm.
13. Unfasten and remove steering gear from inside car.

1961 Ford With One-Piece Worm Shaft

1. Remove Pitman arm.
2. If necessary, disconnect exhaust pipe from manifold.
3. Remove steering gear housing attaching bolts. *If car has a flexible joint at the steering shaft, remove flexible joint clamp bolt and remove the gear.* Otherwise continue with the following steps.
4. With automatic transmission, disconnect neutral switch wires at switch.
5. Loosen steering column lower clamp.
6. Disconnect shift levers from rods.
7. Remove steering wheel, disconnect horn and turn signal wires and remove steering shaft upper bearing sleeve and spring.
8. Disconnect steering column-to-instrument panel bracket and remove selector dial indicator cover and control indicator.
9. After removing screws from steering column weather seal, position both halves of steering column opening cover plate out of the way.
10. Remove steering column tube assembly and then remove steering gear through passenger compartment.
11. Reverse foregoing procedure to install gear.

Late 1961 and 1962 With Two-Piece Worm Shaft

1. Remove steering column bracket bolts.
2. Disconnect pitman arm from sector shaft.
3. If necessary, disconnect muffler inlet pipe.
4. Unfasten gear housing from frame and remove gear.

1958 Edsel

The steering gear worm is integral with the steering shaft on some models. On other models, a "stub" type worm shaft is used and is connected to the steering shaft by means of an internally splined coupling.

Stub Shaft Gear

1. Disconnect turn signal wires at the bullet type connectors located behind the instrument panel to the left of the steering column.
2. Remove the three screws which attach the selector switch terminal block to the lower side of the steering column tube, then lift off the block assembly.
3. Remove the steering column upper bracket cap, then move the column and wheel assembly upward and rearward to remove it from the car.
4. Remove the sector shaft (pitman) arm from the shaft, using a suitable puller.
5. Remove steering gear-to-frame attaching bolts and remove the steering gear.
6. Reverse the foregoing procedure to install the gear.

Long Shaft Gear

1. Remove steering wheel.
2. Disconnect turn signal wires under the instrument panel.
3. Disconnect automatic transmission neutral switch wires (if equipped).
4. Slide rubber weather seal up on steering column and fold floor mat away from column.
5. Disconnect speedometer cable at speedometer.
6. Remove clutch pedal release rod, clutch equalizer shaft, bushing and bracket.
7. Remove floor panel cover plate.
8. Remove sector shaft (pitman) arm with suitable puller.
9. Disconnect transmission or gear shift rods from levers on steering column.
10. Remove steering gear housing-to-frame attaching bolts.
11. Remove steering gear through front passenger compartment.
12. Reverse foregoing procedure to install the steering gear.

1959-60 Edsel

1. Remove steering wheel.
2. Disconnect turn indicator wires under instrument panel.
3. Remove two screws that fasten steering column bracket to instrument panel.
4. Remove turn indicator lever and gearshift lever from steering column.

5. Remove retaining screws from steering column weather seal on engine compartment wall and fold floor mat away from steering column.
6. Disconnect speedometer cable from instrument panel, remove right-hand cover plate and feed cable through cover plate.
7. Disconnect clutch pedal release rod at pedal and remove plate from rod.
8. Disconnect clutch return spring.
9. Disconnect gearshift linkage at steering column bracket.
10. Remove pitman arm from steering shaft.
11. Unfasten steering gear from frame and remove gear through engine compartment.
12. On cars with automatic transmission, remove selector dial indicator cover and control selector indicator. Disconnect neutral switch wires at bottom of steering column.
13. Reverse removal procedure to install.

MANUAL STEERING GEAR REPAIRS

1958-62

1. Rotate steering worm until nut is in center of travel, Fig. 7.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined below:

Adjustments, Fig. 8

1. Disconnect steering relay rod from pitman arm.
2. Loosen sector shaft lash adjuster screw a few turns to relieve load from bearings.
3. Turn steering wheel in one direction until stopped by gear, then back away about one turn.
4. With a spring scale hooked to rim of steering wheel, measure pull required to keep wheel in motion; this should be ¼ to ¾ lbs. on a 9" radius. If not within these limits, adjust worm bearings as follows:
5. Loosen worm bearing adjuster lock nut and turn adjuster until there is no perceptible end play in worm. Check pull at wheel rim, readjusting as required to obtain proper pull. Tighten lock nut and recheck pull.
6. After worm bearing adjustment is completed and all mounting bolts tightened, adjust sector shaft end play.
7. With steering wheel in straight-ahead position, turn lash adjuster screw clockwise to remove all lash and tighten lock nut.
8. Check pull at rim of steering wheel, taking highest reading on scale as wheel is turned through the central or straight-ahead position. This should be between 1 to 1⅝ lbs. *If more than 1⅝ lbs., turn lash adjuster screw counterclockwise, then come up on the adjustment in a clockwise motion.*
9. Tighten lock nut and recheck pull.

Fig. 8 Steering gear adjustment points. 1958-62

1955-57 Adjustments

Before proceeding with the adjustments, loosen the gear housing from the frame side rail to relieve any possible vertical strain. Loosen the steering column clamp to relieve any possible horizontal strain. Then tighten the mounting and clamp bolts which will relieve any misalignment in the steering gear mounting.

Steering gear adjustments must be made in the order given below to insure satisfactory results.

Worm Bearing Preload

The worm bearing preload is controlled by the shim pack installed between the steering gear housing and the housing upper cap. The shim pack contains shims of various thicknesses; the thinner shims are installed on the top of the pack, and the adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Turn the steering

Fig. 7 Disassembled view of late 1961 and 1962 steering gear with two-piece worm shaft. This unit is the same as 1958-60 and early 1961 except that a one-piece worm shaft is used on the earlier gear

wheel two complete turns from the straight-ahead position. Hook a spring scale to the steering wheel rim. Rotate the wheel at least one turn with the aid of the scale. The pull required to keep the wheel moving should be between ⅛ and ⅝ lbs., which is the worm bearing preload. If the reading is high, a shim or shims should be added. If reading is too low, remove a shim or shims.

If an adjustment is required, unfasten the upper cap from the housing and work the cap and column jacket upward to allow clearance for removing or adding shims. For additional working clearance it may be necessary to remove the steering wheel.

To add a shim, split the shim at one point and install the shim with the split in the upward position. Make sure the split ends do not overlap as this could lead to a false adjustment.

To remove a shim separate the first shim from the pack with a knife blade. Pass the blade all around the shim, being careful not to damage the shims.

The steering column and upper housing cap must be assembled on the gear housing each time the preload is checked.

Worm & Roller Mesh

This adjustment is controlled by the adjustment screw mounted on the sector shaft cover. Adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Attach a spring scale to the steering wheel rim. Pull the wheel through the straight-ahead position and note reading on scale. The scale reading should be at least ½ lb. above that of the worm bearing preload previously determined, but the total reading must not exceed 1⅝ lbs. If the scale reading does not exceed the worm bearing preload by at least ½ lb., the worm and roller mesh should be adjusted.

Place the steering wheel in the straight-ahead position. Remove the adjusting screw cover and lock washer. Rotate the adjusting screw clockwise while moving the steering gear arm back and forth until all backlash is removed.

Install the lock washer and cover and check the preload with the spring scale as previously described. The reading should be between 1 and 1⅝ lbs. If the reading is too high, turn the adjusting screw slightly counterclockwise. If too low, turn the screw slightly clockwise.

Disassemble

Fig. 6 illustrates the conventional steering gear used on 1956 models. But inasmuch as it is typical of earlier models the following procedure will mainly apply to these models.

1. Drain lubricant from housing.
2. Remove sector shaft and cover.
3. Remove cover from sector shaft.
4. Unfasten and slide housing cap off steering shaft.
5. Pull shaft out of housing.
6. Slide housing upper cap gaskets (shim pack), bearing cup, and upper worm bearing out of housing.
7. Use suitable puller to remove lower worm bearing cup.
8. Press sector shaft needle bearings and oil seal through steering arm end of housing.

Fig. 9 Linkage type power steering

Inspect & Assemble

After cleaning all parts, inspect worm and rollers for scores, cracks or for signs of chipping. Inspect steering shaft bearing cups and bearings for wear, cracks or damage. Check sector shaft for wear at needle bearing locations. Replace all parts that are damaged enough to impair steering gear operation, and assemble the steering gear in the reverse order of disassembly.

INTEGRAL POWER STEERING

1961-62 Thunderbird

The Ford Torsion Bar Power Steering unit is used. For repairs see the *Power Steering Chapter*. The following material outlines the removal and installation procedure.

Fixed Column Type

1. Disconnect hydraulic lines from gear housing. Plug openings and cap lines.
2. Disconnect steering shaft flexible joint by driving out tapered pin that retains joint flange to steering shaft.
3. Raise car and disconnect pitman arm from steering gear.
4. Remove gear housing bolts and remove gear.
5. Reverse removal procedure to install steering gear. Then, with engine idling, check for leaks by twice cycling steering wheel from one extreme to the other. Do not hold wheel against the stops. Add fluid to reservoir as required.

Movable Column Type

1. Disconnect hydraulic lines from gear housing. Plug openings and cap lines.
2. Remove 5 pivot bracket clamp bolts, remove bracket upper nut and remove pivot bracket.
3. Remove steering shaft retainer pin.
4. Disconnect pitman arm from steering gear.
5. Remove attaching bolts and remove gear from car.
6. Reverse removal procedure to install gear. Then with engine idling, check for leaks by twice cycling steering wheel from one extreme to the other. Do not hold wheel against stops. Add fluid to reservoir as required.

LINKAGE TYPE POWER STEERING

The power steering system, Fig. 9, combines a conventional type steering gear with a power-assisted steering linkage. The power-assist mechanism consists of a pump and fluid reservoir, a control valve, a power cylinder, the connecting fluid lines and the steering linkage. Figs. 9 to 12 illustrate the main components of the system.

Before performing service operations on the power steering system, make certain that the trouble is not caused by the lack of fluid.

Fluid Pressure Test

A fluid pressure test will show whether the pump or some other unit in the power steering system is causing trouble in the system. Disconnect the pressure line hose from the pump outlet and install a pressure testing tool between the hose and pump outlet. *Be sure the pressure gauge is between the pump and shut-off valve on the tool.*

Open the shut-off valve on the testing tool and run the engine at idle speed. If the pump normally operates quietly, ignore the louder pump noise when the tester is connected to the system. Allow at least two minutes for the fluid to warm up before starting the pressure tests.

1. Turn the front wheels all the way to the right, then to the left, and note

Fig. 10 Power steering pump and reservoir

the fluid pressure reading on the gauge when the wheels are against the stops. Normal fluid pressure at both positions is 975-1100 lbs. *Do not hold the wheels against the stops for more than 30 seconds at a time as the fluid may overheat.*

2. If the fluid pressure is less than specified with the wheels against the stops, turn the wheels away from the stops. Slowly close the tester shut-off valve and watch the gauge for an increase in pressure. *Do not leave the valve closed for more than 15 seconds.*
3. If the fluid pressure is less than specified with the shut-off valve closed, the pump is causing the trouble. If the pressure increases but does not reach the minimum pressure specified, the pump, control valve and the power cylinder all should be inspected. If the pressure is within limits, the trouble is either in the control valve or the power cylinder.
4. After completing the test, shut off the engine, remove the tester and make the necessary repairs.

Pump Removal

1. Remove reservoir cover and draw as much fluid from the reservoir as possible with a suction gun.
2. Disconnect hoses at pump and reservoir and fasten them in a raised position to prevent fluid draining out.
3. Remove pump drive belt.
4. Unfasten and remove pump.

Pump, Install

1. Mount pump on engine and install attaching bolts finger tight.
2. Install and tighten drive belt.
3. Check alignment of crankshaft pulley with pump pulley. If two pulleys are not aligned, the pump may be incorrectly installed or it may be necessary to install spacers to align the pulleys.
4. Adjust pump belt tension as outlined below.
5. Connect hoses at pump and reservoir.
6. Fill reservoir with automatic transmission fluid to ½″ from top of reservoir.
7. Start engine and run at idle speed for about two minutes to warm up fluid in steering system.
8. Turn steering wheel to right and left extremes several times.
9. Check system for fluid leaks.
10. Increase engine speed to a fast idle and again turn steering wheel to both extremes several times.
11. Stop engine and check entire steering system for leaks.

Pump Belt Tension

1. Check belt tension with a torque wrench and socket on the pump pulley bolt. Pull the wrench slowly as if tightening the bolt. The torque required to slip the pulley against the belt friction should be within 14-16 lbs. ft.
2. If the belt is too loose or too tight, loosen the bracket adjusting bolts enough to permit moving the pump and bracket.
3. Reposition the pump until the pulley slips against the belt friction within 14-16 lbs. ft. torque. The belt tension should be as close as possible to the higher torque limit.

Control Valve Removal

1. Remove reservoir cover and, using a suction gun, draw as much fluid as possible from reservoir.
2. Disconnect four hoses at control valve and drain fluid from hoses.
3. Turn front wheels to extreme right and left several times to force all fluid from system.
4. Loosen clamp bolt and nut at right-hand end of sleeve.
5. Pull roll pin out of steering arm-to-idler arm rod through slot in sleeve.
6. Remove control valve ball stud nut.
7. Remove nut from end of ball stud, then raise control valve high enough to remove ball stud from sector shaft arm.
8. Turn wheels fully to left, then turn control valve counterclockwise to remove it.

Control Valve, Install

1. Thread valve on steering arm-to-idler arm rod until about four threads are still visible on the rod.
2. Position ball stud in sector shaft arm.
3. Measure distance between center of ball stud in sector shaft arm and the center of the stud at the inner end of the left-hand spindle connecting rod. *Be sure that measurement is taken parallel to the centerline of the control valve.* The distance should be as follows:

Ford 1961-62	11 15/16″
1960	12″
1957-59	10⅞″
1954-56	9″
Thunderbird 1960	10¾″
1959	9½″
1958	10⅞″
1955-57	9½″
Edsel 1960	11 15/16″
1959	10 15/16″
1958 Ranger, Pacer	10⅞″
1958 Citation, Corsair	11¼″

4. When the correct distance is obtained, install the roll pin in the rod hole to lock the valve on the rod.
5. Tighten the valve sleeve clamp bolt to 30-35 lbs. ft. torque.
6. Install and tighten ball stud nut to a torque of 56-60 lbs. ft.
7. Connect and tighten four hoses on control valve.
8. Fill fluid reservoir to within ½″ from top with automatic transmission fluid.
9. Start engine and run at idle speed for about two minutes to warm up fluid.
10. Turn steering wheel to both extremes several times and check for leaks.
11. Increase engine speed to a fast idle and again turn steering wheel several times to both extremes.
12. Stop engine and check system for leaks.
13. Hook a spring scale to steering wheel rim and measure pull required to turn wheel in both directions with engine idling and wheels on dry concrete. The pull should be about equal in both directions with tires inflated at specified pressures.

Power Cylinder Removal

1. Disconnect the two hoses from power cylinder. Fasten open ends of hoses in raised position to prevent fluid draining out.
2. Place a container under the ports of the power cylinder, then slowly

Fig. 11 Power steering control valve

Fig. 12 Power steering power cylinder

move the front wheels to the left and right several times to force fluid from cylinder.

3. Remove nut, washer and insulator from outer end of piston rod. Do not remove rod from idler arm bracket at this time.
4. Remove nut, washer and insulator from end of stud in steering arm-to-idler arm rod.
5. Pull piston rod out of idler arm bracket and remove power cylinder.

Power Cylinder, Install

1. Install inner washer and bushing on mounting stud in steering arm-to-idler arm rod.
2. Install inner insulator and washer on power cylinder piston rod, then position the cylinder on the mounting stud with the piston rod in the idler arm bracket.
3. Install outer bushing, washer and nut on mounting stud. If a new nut is installed, tighten it to a torque of 60-70 lbs. ft. If a used nut is installed, tighten it to 50-60 lbs. ft.
4. Install the outer insulator, washer and nut on the piston rod, and tighten the nut to a torque of 40-50 lbs. ft.
5. Connect and tighten two hoses to control valve.
6. Fill reservoir to proper level.
7. Start engine and run at idle speed for about two minutes to warm fluid.
8. Turn steering wheel to right and left extremes several times and check system for fluid leaks.
9. Increase engine speed to a fast idle and again turn steering wheel to both extremes several times.
10. Stop engine and check for fluid leaks.

Speedometer, Radio and Windshield Wiper

SPEEDOMETER, REPLACE

1955

1. Remove speedometer dome (4 nuts).
2. Remove temperature and fuel gauges.
3. Remove speedometer back plate (4 screws).
4. Unfasten front housing from upper housing (2 screws) and remove front housing.
5. Remove lower housing (2 screws).
6. Speedometer may now be removed from upper housing (2 screws).

1956

Disconnect speedometer cable and remove four speedometer mounting screws. Rotate speedometer ¼ turn clockwise and remove it from cluster.

1957 All, 1958-60 Ford

Remove instrument cluster from front of panel. Remove cluster back plate. Speedometer may now be removed.

1958-60 Thunderbird

Pull speedometer bezel from instrument panel. Remove four mounting screws and pull speedometer far enough from panel to disconnect cable and remove pilot lights.

1961-62 Ford

1. Disconnect battery cable.
2. Remove instrument cluster.
3. Unfasten and remove speedometer from instrument cluster.

1961-62 Thunderbird

Remove screw retaining chrome trim ring and remove ring. Remove mounting screws and pull speedometer far enough from instrument panel to disconnect cable and remove pilot lights.

Make certain all pilot lights are secure in their mounting holes when installing speedometer. The top pilot light is the high beam indicator.

1958 Edsel

1. Disconnect battery ground cable.
2. Unfasten left-hand fresh air duct from instrument panel.
3. Lower duct, remove cable and remove duct.
4. Remove speedometer light sockets.
5. Disconnect cable housing from speedometer.
6. Unhook wiring harness from clips and move harness downward out of the way.
7. Unfasten speedometer (4 screws), tip unit downward and remove from rear of cluster.

1959 Edsel

1. Disconnect battery ground cable.
2. Remove hi-beam indicator and speedometer lamp socket and bulb assemblies.
3. Remove oil pressure and charge indicator lamp sockets and bulbs.
4. Disconnect speedometer cable.
5. Disconnect two wires from constant voltage (C.V.) regulator.
6. Remove five screws from speedometer retainer plate and carefully remove speedometer from cluster.

1960 Edsel

1. Remove upper instrument cluster.
2. Remove six speedometer case-to-cluster screws and remove speedometer and case.
3. Remove speedometer from case.

RADIO REPLACE

1960-62 Ford

1. Pull off radio knobs and remove nuts retaining radio to instrument panel.

2. Disconnect antenna lead at right side of radio.
3. Disconnect speaker leads and pilot light wire at wiring harness.
4. Disconnect radio lead wire at fuse panel and wire from retaining clips.
5. Remove radio support bolt and nut.
6. Lift radio out of instrument panel.
7. Reverse removal procedure to install.

1960-62 Ford Air Conditioned

Remove the glove box liner, radio speaker, right radio mounting support and then lift the radio through the speaker opening.

1955-59 Ford
1955-57 Thunderbird

1. On 1957-58, remove right-hand air duct.
2. On all models, disconnect antenna, lead from right side of radio and speaker connector at back side.
3. Disconnect pilot light wire and "A" lead from radio.
4. Remove fuse and two panel mounting screws.
5. Remove nut from stud on each side of radio and press brackets away from studs.
6. Push radio forward and tilt it toward toeboard until it clears instrument panel.

1958-60 Thunderbird

Radio Receiver — Remove the control knobs and two mounting nuts. Remove radio access cover and rear support bracket-to-instrument panel mounting bolt. Lower receiver through access hole and disconnect pilot light lead, "A" lead and audio chassis cable.

Audio Chassis—To gain access, remove left heater control trim panel extension. Disconnect audio chassis cable from receiver control chassis. Disconnect speaker and remove chassis (4 screws).

Speaker—Remove heater control trim panel and tunnel trim panel. Remove four mounting nuts and disconnect speaker cable from audio chassis and remove speaker.

1961-62 Thunderbird

1. With ignition switch off, remove speaker grille and speaker.
2. Remove control knobs, two hex mounting nuts, the bezel, and two radio mounting nuts and washers.
3. Remove radio access cover and radio lower center support screw.
4. Remove radio through speaker opening.

1958 Edsel

1. Remove both fresh air ducts from under instrument panel.
2. Disconnect antenna and speaker wires from radio. *Never turn radio on while speaker is disconnected as this will damage the transistors.*
3. Disconnect pilot light at bullet connector and the "A" lead at fuse panel.
4. Remove control knobs, serrated ring controls, bezel and radio retaining nuts.
5. Remove bracket nuts from each side of radio and press brackets away from studs.
6. Work radio out of instrument panel, then tilt it toward toeboard until unit clears instrument panel.

1959 Edsel

1. Disconnect ground cable from battery.
2. Disconnect dial lamp and "A" power lead at quick disconnect.
3. Remove front speaker plug, and rear speaker plug if so equipped, from rear of receiver.
4. Disconnect audio unit cable plug from rear of chassis.
5. Disconnect antenna lead in cable at bottom of chassis.
6. Remove tuning, volume, tone and speaker knobs.
7. Remove escutcheon (2 nuts).
8. Remove two control shaft nuts.
9. Remove radio (nut on each side).
10. *On air conditioned cars it will be necessary to remove glove box, clock, ash receiver and evaporator cover plate. Radio may then be removed from under right side of instrument panel.*

1960 Edsel

1. Disconnect battery ground cable.
2. Remove control knobs, nuts and washers from front of radio.
3. Disconnect antenna lead-in cable and front seat speaker plug.
4. Disconnect dial lamp wire at bullet connector and "A" power lead at fuse mounting block.
5. Remove nut from radio bracket at right side and screw from bracket at left side. Then remove radio. *On cars with air conditioning, it is necessary to remove ash tray and spot cooler.*
6. To install, reverse removal procedure.

WINDSHIELD WIPER

1955-56

1. To remove wiper motor, first take out radio.
2. Remove linkage and vacuum line from motor.
3. Remove motor from mounting bracket (2 screws).
4. Remove cable from motor.

1957

The wiper motor operates through two sets of cables. Tension on the cables is maintained by two cable tensioners. The wiper motor is removed in the same manner as on earlier models except that the radio *need not* be removed. To remove the cables and tensioners, it will be necessary to remove the cowl top ventilator grille and weatherstrip.

To assemble the cables, first connect them to the motor pulley. Pull the cable tension ratchet spring away from the ratchet, wind up the cable tension spring and insert a cotter pin in the hole temporarily. Position cables over tension pulleys and install tensioners. Remove holding cotter pin, install pivot shaft idler pulley water shields, and ventilator grille and weatherstrip.

1958 Ford

When service is required on the wiper motor, control assembly or pivot shaft assemblies, they may be removed separately. To gain access to the motor and linkage, however, first take out the radio and remove the cowl top ventilator grille and weatherstrip.

1959 Ford

To remove the motor and mounting plate, first disconnect the pivot shaft links from the motor shaft arm (under instrument panel). On vacuum motor jobs disconnect control cable and vacuum hose. On electric motor jobs disconnect control cable and motor supply wire. Remove motor and mounting plate (2 nuts).

The control assembly may be removed from the instrument panel by removing the bezel nut after loosening and removing the control knob.

To remove the pivot shafts, first lift off the wiper arms and blades. Remove the link retaining clips from the motor shaft. Remove pivot attaching nuts, spacers and washers. The pivots may then be removed.

1960-62 Ford

To remove the wiper motor on car with air conditioner, remove the glove box liner, radio, speaker, and right defroster nozzle-to-instrument panel brace (if equipped). Then remove the wiper motor through the speaker opening.

To remove the wiper motor on cars without air conditioning, proceed as follows:

1. Remove two bolts retaining motor and lower the motor.
2. Disconnect wiper motor vacuum line at motor or at bullet connector.
3. Loosen screw retaining wiper control cable at motor and disconnect cable.
4. Reverse above procedure to install motor and adjust control cable.

1958-60 Thunderbird

When service is required on the wiper motor, control assembly or pivot shaft assemblies, they may be removed separately. To remove any of the wiper assemblies it will first be necessary to remove the glove box. To remove the wiper motor, in addition to the glove box, the right defroster air duct must also be removed. And to gain access to the left pivot shaft the speedometer must be removed.

Before installing a new wiper motor, loosen the motor drive pulley tension clamp nut, compress the tension arms and tighten the nut. When the motor is installed, loosen the tension arms clamp nut to put tension on the cables then tighten the nut.

Before installing new pivot shaft assemblies, loosen the motor drive pulley tension arms clamp nut, compress the tension arms with a "C" clamp and tighten the nut. After installing the cables and pivot shafts, release the tension arms clamp nut, then tighten it.

1958-59 Edsel

If service is required on the wiper motor, control assembly or pivot shaft and cable tensioners, they can be removed separately. Removal of the wiper motor and control assembly is obvious. The following outlines the requirements on the pivot shaft and cable tensioners:

1. Remove nine screws and lift off cowl top ventilator grille.
2. Remove rubber plugs from access holes in cowl panel above cable tensioners.
3. Remove nuts and screws from tensioner mounting brackets. Remove tensioners from cowl panel, leaving them in cowl compartment.
4. Remove wiper arms and blades.
5. Unfasten and lower pivot assemblies into cowl compartment.
6. Reach through cowl top ventilator opening and disconnect cables from auxiliary drive.
7. Remove wiper pivot and cable and tensioner assemblies from cowl compartment.
8. Bend cable guide tabs slightly to release cables from tensioner pulleys. *The cable tensioner always winds to its tightest position when cables are removed from pulleys. Therefore, it is important that the tensioners be reset before they are installed.*
9. Clamp the tensioner in a vise to preset the spring. While holding the leaf spring away from the ratchet, wind up the cable tension spring until the locking pin hole is in line with the bracket. Insert a cotter pin in the hole to hold the tensioner in the preset position temporarily.
10. Install the cables on the pulleys and bend cable guide tabs to their original position so that they barely clear the pulleys.
11. Install the assemblies, *noting that the cable tips and cable attaching tabs on the auxiliary drive pulley are color coded to facilitate assembly of cables in proper grooves on the drive.*
12. When installed and tightened, insert a hooked tool through the access hole in the cowl and pull the cotter pins out of the tensioners.

1960 Edsel

1. Disconnect battery ground cable on cars with electric wiper and/or air conditioning.
2. Disconnect control cable from motor.
3. Disconnect vacuum hose from motor, and windshield washer control cable (if equipped).
4. Unfasten and remove wiper motor from dash panel.
5. On air conditioned cars, remove radio and spot cooler in order to remove wiper motor.
6. Reverse above procedure to install.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness. On aluminum engines, none of these bolts, including the cylinder head bolts, should be re-tightened with the engine at normal operating temperature.

Engine Section

ENGINE MARKINGS

The letter "A" immediately following the engine number indicates .020" oversize cylinder bores.

The letter "B" immediately following the engine number indicates .010" undersize crankshaft journals.

The letters "AB" immediately following the engine number indicates .020" oversize cylinder bores and .010" undersize crankshaft journals.

A maltese cross ⅜" high stamped on engine numbering pad indicates that one or more connecting rods and main bearings are finished .001" undersize.

A diamond shaped mark stamped on engine numbering pad indicates that all valve lifter bodies are .008" oversize.

ENGINE, REPLACE

1. Scribe hood hinge outlines on hood and remove hood.
2. Drain cooling system and remove battery and carburetor air cleaner.
3. Disconnect transmission cooler lines at radiator (if equipped).
4. Remove radiator and hoses.

5. Remove outlet vent pipe.
6. Disconnect fuel lines, carburetor linkage and wiring to engine.
7. Disconnect exhaust pipe at manifold.
8. Disconnect propeller shaft and tie out of the way.
9. Remove speedometer cable and gear-shift rods.
10. Remove clutch torque shaft, brake cables and rods.
11. Remove converter cover plate.
12. Drain converter and transmission. Remove oil cooler lines, filler tube and push button cable.
13. Support rear of engine.
14. Remove engine rear support cross-member.
15. Disconnect converter from flexible mounting plate.
16. Remove transmission bolts from clutch housing.
17. Remove transmission and converter as an assembly. *Do not remove converter from transmission.*
18. Attach lifting fixture to cylinder head and attach chain hoist.
19. Remove engine support and front engine mounting bolts and lift engine from chassis.
20. Reverse above procedure to install.

Lancer and Valiant engine

CYLINDER HEAD

1. To remove head, drain cooling system.
2. Remove carburetor air cleaner and fuel line.
3. Disconnect accelerator linkage.
4. Remove vacuum control tube at carburetor and distributor.
5. Disconnect spark plug wires, heater hose and clamp holding by-pass hose.
6. Disconnect heat indicator sending unit wire.
7. Disconnect exhaust pipe at manifold.
8. Remove intake and exhaust manifold and carburetor as a unit.
9. Remove outlet vent tube and rocker arm cover.
10. Remove thermostat housing and thermostat.
11. Remove rocker arms and push rods.
12. Remove head bolts and lift off head.
13. Check all surfaces of head with a straightedge if there is any reason to suspect leakage. *Cylinder head warpage should not exceed .005" lengthwise or .003" crosswire.* If there is any reason to suspect restricted water passages, the large recessed screw plug in the rear of the head can be removed.
14. Clean the oil return passages in the head and block.
15. Install the head in the reverse order of removal and tighten the bolts in the sequence shown in Fig. 3 and to the torque listed in the *Engine Torque* table.
16. *When installing the manifolds, loosen the three bolts holding the intake manifold to the exhaust manifold. This is required to maintain proper alignment.* Install intake and exhaust manifold with carburetor with the cup side of the conical washers against the manifolds. Tighten the nuts to 10 ft. lbs. Then tighten the three bolts holding the intake manifold to the exhaust manifold to 15 ft. lbs.

Fig. 2 Internal parts of engine

VALVE ARRANGEMENT

Front to Rear

6 Cyl. ..... E-I-E-I-E-I-I-E-I-E-I-E

Fig. 3 Cylinder head tightening sequence

VALVES, ADJUST

Before the final valve lash adjustment is made, operate the engine for 30 minutes at a fast idle to stabilize engine temperatures.

Before starting the adjustment procedure, make two chalk marks on the vibration damper. Space the marks approximately 120° apart (⅓ of circumference) so that with the timing mark the damper is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

Service Note

To adjust valves on aluminum engines, first run the engine until normal operating temperature is reached. Then remove the rocker arm cover. After the rocker arm cover has been removed, run the engine an additional five minutes at idle speed. Then adjust the valves in the usual manner. It is necessary that the foregoing procedure be followed because of the different expansion characteristics of the metals involved.

ROCKER ARMS

1. To remove rocker arms, take off head cover outlet tube.
2. Remove rocker arm cover.
3. Remove rocker shaft bolts and retainers.
4. Lift off rocker arms and shaft.

Inspection

Clean all parts with a suitable solvent. Be sure the inside of the shaft is clean and the oil holes are open. The drilled oil hole in the bore of the rocker arm must be open to the trough and valve end of the arms. The trough also feeds oil to the adjusting screw and push rod.

The shaft should be free from excessive wear in arm contact areas. The shaft should be smooth in retainer contact areas. The adjusting screws in the rocker arms should have a uniform round end. The drag torque should be smooth and uniform. The retainers should be smooth and undamaged in the shaft contact area.

Assemble and Install

1. Referring to Fig. 4, note flat on forward end of rocker shaft which denotes the upper side of the shaft. Rocker arms must be put on the shaft with the adjusting screw to the right side of the engine. Place one of the small retainers on the one long bolt and install the bolt in the rear hole in the shaft from the top side.
2. Install one rocker arm and one spacer; then two rocker arms and a spacer. Continue in same sequence until all rocker arms and spacers are on the shaft.
3. Place a bolt and small retainer in front hole in shaft.
4. Place a bolt and the one *wide* retainer through the center hole in the shaft with six rocker arms on each side of center.
5. Install remaining bolts and retainers, separating the four pairs of rocker arms.
6. Locate the assembly on the cylinder head and position rocker arm adjusting screws in push rods.
7. Tighten bolts finger tight, bringing retainers in contact with the shaft *between rocker arms.*
8. Tighten bolts to 30 ft. lbs.
9. After running engine to normal operating temperature, adjust valve lash to specifications.
10. Complete the job by installing the remaining parts removed.

Fig. 4 Rocker arm and shaft assembly

Fig. 4A Checking installed height of valve spring

VALVES, REMOVE

Place the cylinder head on its side and, with a suitable valve spring compressor, compress the valve spring and remove the valve locks. Release the tool and remove spring retainer and spring. Remove any burrs or sharp edges on the valve stem before removing the cup seal and valve. As the valves are removed, keep them in a numbered board or rack in the same order as they were in the head so they will be in proper sequence for inspection and assembly.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure all carbon is removed

from the top and bottom of the valve heads as well as the gum which might have accumulated on the valve stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too sharp or thin due to excessive grinding, the valve must be scrapped. This condition leads to premature breakage, burning and pre-ignition due to the heat localizing on this knife edge. If the edge of the valve head is less than $\frac{3}{64}$" thick after grinding, discard the valve.

Reface intake valves to 45 degrees and exhaust valves to 47 degrees. Reseat the cylinder head to 45 degrees for both intake and exhaust valves.

Try each valve (with Prussian Blue) in its proper seat to determine the contact with the seat. The position of the contact should be near the center of the reground area of the valve and the seat should be $\frac{5}{64}$" to $\frac{3}{32}$" wide for intake, and $\frac{3}{64}$" to $\frac{1}{16}$" for exhaust valves. To move the contact toward the head of the valve (and narrow the seat) use a 60-degree stone. To move the contact away from the head of the valve (and narrow the seat) use a 20-degree stone.

VALVE GUIDES

Valves operate in guide holes bored directly in the cylinder head. When valve stem-to-guide clearance becomes excessive, valves with oversize stems of .005" .015" and .030" are available for service replacement. When necessary to install valves with oversize stems the valve bores should be reamed to provide the proper operating clearance.

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004" on the intake or .005" on the exhaust, ream the guides to accomodate the next oversize diameter valve stem.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to he coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 4A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Fig. 5 Valve timing marks aligned for correct valve timing

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is $\frac{1}{16}$", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

Wash all springs with a suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, and according to the specifications listed in the *Valve Specifications* table. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be discarded. Likewise, any spring that stands shorter than the new spring used for comparison should be replaced. Of course, cocked springs should also be scrapped.

VALVE LIFTERS

After taking off rocker arm and shaft assembly, lift out push rods. The valve lifters may then be removed with a suitably long magnet rod. If the lifters cannot be removed with the magnet rod, a special tool (C-3661) may be used. Insert the tool through the push rod opening in the cylinder head and into lifter. Turn the handle to expand the tool in the lifter, then with a twisting motion remove the lifter from its bore. Place lifters in a board with numbered holes since each lifter must be installed in its original location.

Inspect the lifters for scores and the lower ends for pits and rough surfaces. Check crowned faces of lifters with a straightedge. If any negative crown (dish) is observed, the lifter should be replaced.

Service Note

In the aluminum engine, the valve lifters operate in machined bores in the engine and may be rebored to accommodate oversize lifters of .001", .008" and .030".

TIMING CHAIN COVER

1. To remove cover, drain cooling system and remove radiator and fan.
2. Remove vibration damper with a puller.
3. Loosen oil pan bolts to allow clearance and remove chain case cover.
4. Reverse above procedure to install cover.

TIMING CHAIN

1. After removing chain case cover as outlined above, take off camshaft sprocket attaching bolt.
2. Remove chain with camshaft sprocket.
3. Clean all parts and dry with compressed air.
4. Inspect timing chain for broken or damaged links. Inspect sprockets for cracks and chipped, worn or damaged teeth.

Installation

1. Turn crankshaft so sprocket timing mark is toward and directly in line with centerline of camshaft.
2. Temporarily install camshaft sprocket. Rotate camshaft to position sprocket timing mark toward and directly in line with centerline of crankshaft; then remove camshaft sprocket.
3. Place chain on crankshaft sprocket and position camshaft sprocket in chain so sprocket can be installed with timing marks aligned without moving camshaft, Fig. 5.
4. Install parts removed in reverse order of removal.

CAMSHAFT & BEARINGS

In the aluminum engine the camshaft bearings are an integral part of the cyl-

Fig. 6 Camshaft and sprocket

inder block casting and are not replaceable.

In the cast iron engine, the camshaft is supported by four precision type, steel-backed, babbitt-lined bearings. Rearward thrust is taken by the rear face of the sprocket hub, contacting the front of the engine block.

The camshaft, Fig. 6, can be removed after removing the grille, radiator and timing chain. To remove the camshaft bearings, the torque converter (or flywheel) must also be removed.

1. Remove valve lifters, oil pump and distributor.
2. Slide camshaft out of engine.
3. Remove welch plug back of rear camshaft bearing.
4. Remove bearings with suitable puller equipment.
5. Install new bearings, being sure the oil holes in bearings line up with the corresponding oil holes in the crankcase.

PISTONS & RODS, REMOVE

1. Drain cooling system and remove the cylinder head.
2. Drain oil and remove oil pan.
3. Remove top ridge from cylinder bores, using a suitable ridge reamer.
4. Rotate crankshaft so connecting rod being removed is centered with cylinder bore; then remove rod cap.
5. Use protector sleeves over connecting rod bolts and push pistons and rods out through top of cylinder block.
6. Install caps on their mating rods.

PISTON & ROD, ASSEMBLE

Piston and rod assemblies must be installed with the notch on the piston head toward the front of the engine, and the oil hole in the connecting rod toward the manifold side of the engine.

PISTONS

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

Service Note

The cylinder block for the aluminum engine is die-cast aluminum with cast-in-place iron cylinder bore liners .100″ thick. The liners are not replaceable. When conditions require reboring, the cylinder can be rebored up to a maximum of .040″ oversize. After reboring, do not re-chamfer the liner top so that the sealing surface at the top of the liner is maintained.

PISTON PINS

Piston pins should be a very light thumb press fit in the piston with the parts at room temperature (70°). Piston pins are supplied in standard size only. If excessive clearance is noted, both piston and pin should be replaced.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is

Fig. 7 Checking bearing clearing with Plastigage

Fig. 8 Oil Pan and gaskets

available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 7. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque* table.

Service Note

Servicing of main bearings in aluminum engines is identical to the cast iron engine. However, make certain that any new bearings installed are applicable to the aluminum engine. The oil hole location in the aluminum engine upper main bearings differs from the cast iron engine location. Upper main bearings with two oil holes will fit in both engines, but upper main bearings with one oil hole fit only in the cast iron block.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding end of the seal with sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced, it is possible to do the job without removing the crankshaft as follows:

To remove the old seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being moved.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is being installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN, REPLACE

1960-61

1. Disconnect battery ground cable.
2. Drain cooling system and disconnect both radiator hoses.
3. Loosen alternator adjuster strap and move alternator toward engine as far as possible.
4. Disconnect throttle rod at carburetor by pulling it out of rubber bushing in carburetor lever.
5. Disconnect exhaust pipe at manifold.
6. Disconnect any other tubes, hoses or wires in engine compartment that might interfere or be damaged by raising front end of engine.
7. Remove steering and idler arm ball joints from steering linkage center link.
8. Remove bolts attaching the two engine supports to the "K" member.
9. Using a block of wood positioned under forward end of oil pan (over bolt heads) raise front of engine approximately two inches with a jack against the wood block. *Do not jack up engine under vibration damper.*
10. After engine is raised, place short pieces of 2x4 wood blocks between engine supports and "K" member. Lower engine and remove jack.
11. Remove clutch lower and front covers, or converter cover plate.
12. Drain oil and remove oil pan.
13. Maneuver oil pan down and forward, then lower rear end of pan and remove.
14. Note position of oil screen and pipe; then unscrew the assembly from crankcase.
15. Reverse removal procedure to install the pan, noting the location of the pan gaskets Figs. 8, 8A.

Fig. 8A Tighten oil pan screws to 200 inch lbs. in the sequence shown. 6-225 engine

1962

1. Raise car and drain oil.
2. Pull steering and idler arm ball joints from steering linkage center link.
3. Remove dust shield and motor mount nuts.
4. Lower car and remove horns and mounting brackets. Then disconnect battery ground cable.
5. Raise engine about 2 inches.
6. Again raise car on hoist and remove oil pan.

OIL PUMP, REPLACE

1960-61

In order to gain access to the oil pump, it will be necessary to perform Steps 1 through 10 for removing the oil pan. Then remove oil pump cover, outer rotor and oil pump, Fig. 9.

1962

In order to remove the pump with the K member in place, and without removing the engine, use the following procedure.

1. Disconnect accelerator rod at carburetor.
2. On cars with automatic transmission, the transmission shift rod, which runs from the accelerator rod to the firewall bellcrank, should be disconnected at the bellcrank.
3. Remove wiring harness from hold-down clips under the heater housing and place on top of cylinder head

Fig. 9 Oil pump and filter disassembled

cover in order to avoid crushing the harness between the cylinder head and firewall when the engine is raised.

4. On 6-225 engine, remove heater from firewall. It is not necessary to disconnect heater hoses.
5. Place jack under right front corner of oil pan rail.
6. Remove both front engine mounts.
7. Remove oil filter, oil pump cover, rotor and pump-to-block fastening screws. Rotor is removed to prevent possible damage should it fall out after cover has been removed.
8. Raise engine upward to limit of its travel.
9. Using a pry-bar applied to the right front side of the block, push the engine to the left just far enough to allow the pump shaft to be eased out of the block. The actual pump removal is facilitated by rotating the pump slightly clockwise and then raising up on the pump body when the shaft is almost clear of the block.

OIL PUMP REPAIRS

To disassemble, remove the pump cover seal ring. Press off the drive gear, supporting the gear to keep load off aluminum body. Remove rotor and shaft and lift out outer pump rotor. Remove oil pressure relief valve plug and lift out spring and plunger. Remove oil pressure sending unit.

Inspection

1. The rotor contact area and the bores for the shaft and valve in the pump body should be smooth, free from scratches, scoring or excessive wear.
2. The pump cover should be smooth, flat and free from scoring or ridges. Lay a straightedge across the cover. If a .0015″ feeler gauge can be inserted under the straightedge, the cover should be replaced.
3. All surfaces of the outer rotor should be smooth and uniform, free from ridges, scratches or uneven wear. Discard a rotor less than .649″ thick and/or less than 2.469″ in diameter.
4. The inner rotor and shaft assembly should be smooth, free from scoring and uneven wear. Discard rotors less than .649″ thick.
5. Place outer rotor in pump body and measure clearance between rotor and body. Discard pump body if clearance is more than .012″.
6. Install inner rotor and shaft in pump body. Shaft should turn freely but without side play. If clearance between rotor teeth is more than .010″, replace both rotors.
7. Measure rotor end clearance. If feeler gauge of more than .004″ can be inserted between straightedge and rotors, install a new pump body.
8. The oil pressure relief valve should be smooth, free from scratches or scoring, and should be a free fit in its bore.
9. Relief valve springs are painted either gray, red or brown to denote free lengths of 2.19, 2.29 and 2.39 inches. Rather than change the length, replace a spring with one of the same color.

Assemble and Install

1. With pump rotors in body, press drive gear on shaft, flush with end of shaft.
2. Install seal ring in groove in body and install cover. Tighten bolts to 10 ft. lbs. Test pump for free turning.
3. Install oil pressure relief valve spring. Use new washer (gasket) and tighten plug securely.
4. If pump shaft turns freely, remove pump cover and outer rotor before installation of pump on engine.
5. Install oil pressure sending unit and tighten to 60 inch lbs. (5 ft. lbs.)
6. Using a new gasket, install pump on engine and tighten bolts to 200 inch lbs. (16 ft. lbs.)
7. Install oil filter reservoir on pump. Install filter element and tighten cover nuts to 25 ft. lbs.

Fig. 10 Water pump disassembled

8. Connect oil pressure sending unit wire.
9. Complete the installation by reversing Steps 1 through 10 as given under *Oil Pan, Replace.*

RADIATOR

To remove radiator, drain cooling system and disconnect hoses. On cars so equipped, disconnect oil cooler lines and cap them to prevent loss of fluid. Remove radiator attaching bolts and lift radiator straight up and out of chassis.

WATER PUMP REPLACE

To remove the water pump, drain cooling system and loosen the fan belt. Remove the fan, spacer, pulley and belt. Remove the pump inlet hose and the heater hose. Remove clamp from by-pass hose. Remove water pump bolts and push pump body down and off the by-pass hose.

WATER PUMP REPAIRS

The water pump body and the shaft are serviced only as an assembly. It is not necessary to remove the hub unless a new pump assembly is to be installed. Replacement of the impeller and the seal, Fig. 10, is done as follows:

1. Support pump on the hub end of shaft and break plastic impeller away from metal insert.
2. Remove support plate and gaskets.
3. Split impeller metal insert and remove from shaft.
4. Remove rubber portion of shaft seal and the spring. Use a puller to remove retainer portion of seal, then remove thrower from shaft. *Do not pry retainer portion of seal out of pump body.*
5. Pump shaft should rotate freely without binding and pump body should be free of corrosion and damage. If a new shaft and body is necessary, remove hub from shaft with a puller. To install the hub on new pump, support the pump on the impeller end of the shaft only. Press the hub 13/32″ beyond flush.
6. Complete assembly by reversing the disassembly procedure.

DISTRIBUTOR, REPLACE

The distributor rotates clockwise. To remove, take off cap, disconnect primary wire and vacuum line. Remove hold-down bolt and lift out distributor. Install in the following manner:

1. Rotate crankshaft until mark on inner edge of crankshaft pulley is in line with the "O" (TDC) mark on timing chain cover.
2. With distributor gasket in position, hold distributor over mounting pad.
3. Turn rotor to point forward, corresponding to 4 o'clock position.
4. Install distributor so that when fully seated on engine, the gear has spiraled to bring rotor to 5 o'clock position.
5. Turn housing until ignition points

are separating and rotor is under No. 1 cap tower.
6. Install hold-down bolt.
7. Adjust timing with timing light.

IGNITION TIMING

For initial timing, follow instructions given under *Distributor, Replace.* Then for the final setting, time the engine with a timing light, being sure to disconnect the vacuum advance line to render the advance mechanism inoperative during the timing process.

STARTER, REPLACE

To remove the starter, disconnect negative cable at battery and starter cable at starter. Remove starter-to-flywheel attaching bolts and remove starter and cylinder block seal from beneath engine.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the float and intake needle and seat may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In case where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Do not use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Hesitation On Light Acceleration

1960—If this condition is encountered after an engine tune-up, it can be corrected by repositioning the air cleaner inlet tube at 90° to the right across the valve cover.

Adjusting Idle Speed

1961-62—If a condition of stalling or rough idle is encountered on cars with automatic transmission, adjust the hot idle speed to 500 rpm in Drive *with the headlights on.* It is important to make this adjustment with the headlights on so the alternator will be under full load condition. There is a variation up to 65 engine rpm between "light" and "full" charge conditions of the alternator.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

CARTER CARBURETOR ADJUSTMENTS

CARTER NOTES

Fig. ①—BBS float level. Adjust by bending lip on float arm.

Fig. ③—Open throttle valve and hold choke valve fully closed. Now close throttle valve which will position fast idle cam to fast idle position. Release choke valve only. The index mark on cam should split center of fast idle screw. Adjust by bending fast idle connector rod.

Fig. ②—Open choke valve so that throttle valve can be fully seated in carburetor bore, then close throttle valve lightly. With pump connector rod in center hole of throttle lever, measure distance from top of air horn to end of pump plunger shaft. Adjust by bending pump connector rod.
Note: If pump rod is installed in either long or short stroke hole, remove hair pin clip (directly under bowl vent valve) either up or down to obtain correct bowl vent clearance.

Fig. ④—With throttle valve held wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader tang on throttle lever.

⑤—With engine running and warmed-up, open throttle slightly and rotate fast idle cam to place fast idle screw on second step of cam. Then adjust fast idle screw to obtain engine speed listed.

HOLLEY CARBURETOR ADJUSTMENT

★See Tune Up Chart for hot idle speed.

Year	Model	Carb. Type	Idle Adjustments★				Float Level	Fuel Level	Float Bowl Vent Valve	Pump Override Spring	Choke Unloader	Choke Setting
			Mixture Screws Turns Open	Air Bypass Turns Open	Fast Idle Speed	Dashpot Plunger Clearance						
1962	1920	1 Bore	1	None	①	None	②	11/16③	3/32④	None	⑤	⑥

HOLLEY CARBURETOR NOTES

Fig. ①—With transmission in neutral, engine temperature normalized and fast idle screw on second step of cam, turn adjusting screw in or out to obtain 1300 rpm on manual and 1400 rpm on automatic transmission cars.

Fig. ③—Check actual fuel level through economizer opening with a 6" scale and depth gauge as shown. Level listed is between outer surface of carburetor body to level of fuel.

⑤—With choke plate and throttle plate both closed, index mark on fast idle cam, Fig. ①, should line up with center of fast idle adjusting screw. To adjust, bend fast idle link as required.

Fig. ②—With carburetor inverted, install float gauge. Check setting on "touch" side of gauge. Reverse gauge and check setting on "no touch" side. Adjust float level by bending tab on float lever.

Fig. ④—With throttle closed, bowl vent should be adjusted so that the shank of a drill of the dimension listed can be inserted between valve and surface of carburetor body. Bowl vent operating lever can be bent up or down to provide proper clearance.

Fig. ⑥—The automatic choke includes a vacuum piston in the carburetor and a remote thermostat mounted on the manifold heat well. Remove welch plug with sharp punch to remove choke piston and link for cleaning. Install and set new plug with brass drift.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

Shorten or lengthen the clutch release fork rod by turning the adjusting nut until there is $\frac{5}{32}$" free movement of the clutch fork outer end. This adjustment, if correctly set, will give the necessary one inch free play at the pedal.

CLUTCH SERVICE

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If clutch rebuilding equipment is available, follow the equipment manufacturer's instructions.

Removal

1. Remove transmission and clutch pan.
2. Pull out clutch release bearing and sleeve.
3. Mark clutch cover and flywheel so they may be assembled in the same relative position and thus maintain original balance.
4. Remove capscrews which retain clutch cover to flywheel. Loosen each screw a few turns in succession until cover is free.
5. Clutch assembly and driven disc may now be removed from clutch housing.

Installation

1. Coat pilot bearing in crankshaft with wheel bearing grease.
2. Clean surfaces of flywheel and pressure plate, making certain no oil or grease remains on these parts.
3. Hold cover plate and disc in place and insert a special clutch aligning tool or spare clutch shaft through

Fig. 1 Manual shift transmission

hub of disc and into crankshaft pilot bearing.

4. Bolt clutch cover loosely to flywheel, being sure marks previously made are lined up.
5. To avoid distortion of clutch cover, tighten cover bolts a few turns each in progression until all are tightened securely.
6. Adjust clutch pedal free travel.

MANUAL SHIFT TRANSMISSION

Transmission, Replace

1. Drain lubricant.
2. Disconnect propeller shaft, speedometer cable and housing, gearshift control rods and hand brake controls. *Remove speedometer cable with hand so that housing is not crushed.*
3. Remove back-up light switch.
4. Support rear end of engine.
5. Raise engine slightly and remove crossmember attaching bolts.
6. Support transmission; then remove transmission-to-clutch housing bolts.
7. Slide transmission rearward until clutch shaft clears clutch disc before lowering transmission.
8. Reverse above procedure to install the transmission and adjust gearshift control.

Transmission Repairs

1. Referring to Fig. 1, remove transmission flange.
2. Remove extension housing.
3. Remove transmission cover.
4. Remove clutch shaft bearing retainer.
5. Grasp clutch shaft with hand and pull assembly out of case. *Be careful not to bind inner synchronizer ring on clutch teeth.*
6. With transmission in reverse, remove outer center bearing snap ring, using a hook or a flat blade, then partially remove mainshaft.
7. Cock mainshaft; then remove synchronizer sleeve, rings and 2-3 shift fork.
8. Remove clutch gear snap ring, using snap ring pliers. Slide clutch gear off end of mainshaft.
9. Slide second speed gear, stop ring and synchronizer spring off mainshaft.
10. Remove low-reverse sliding gear and shift fork as mainshaft is withdrawn from case.
11. Using a feeler gauge, check end play of cluster gear, which should be .004″ to .012″ This measurement will determine if new thrust washers are to be installed at reassembly.
12. Drive countershaft rearward and out of case. Remove key from end of shaft.
13. Lift cluster gear and thrust washers out of case. Disassemble cluster gear by removing needle bearings (22 each end) and spacer.
14. Using a suitable drift, drive reverse idler gear shaft towards rear and out of case. Remove key from shaft.
15. Lift out reverse idler gear, thrust washers and needle bearings (22) out of case. Remove needle bearings from gear.
16. To remove gearshift mechanism, remove operating levers from their shafts, Fig. 2.
17. Drive out tapered retaining pin from either of the two lever shafts, then withdraw lever shaft from inside transmission case. *As the shaft is being withdrawn, detent balls will drop to bottom of case.*
18. Remove interlock sleeve, spring, pin and both balls from case. Drive out remaining tapered pin, then slide lever shaft out of transmission.

Assembly Notes

Reassembilng the transmission is accomplished by reversing the disassembly procedure. However, observe the following:

1. When installing the reverse idler gear, have the bevelled ends of the gear teeth forward. Raise the idler gear slightly to align with shaft; then drive shaft into case, through thrust washer and gear, until end of shaft is approximately $\frac{1}{64}$″ below surface of case.
2. Cluster gear thrust washers are

available in two sizes marked "A" and "B". Make a selection to give .004" to .012" total end play of cluster gear. Make sure tabs on thrust washers slide into grooves in case. Countershaft should be installed until approximately $\frac{1}{64}$" below surface of case.

3. When installing mainshaft, have offset of low-reverse fork to rear. Engage fork in low-reverse gear, then position in case by shifting into reverse.
4. After sliding the synchronizer clutch gear on mainshaft and down against second speed gear, select a snap ring of the correct thickness and install. *Snap ring should eliminate end play and must be a snug fit.*
5. Check clearance between clutch gear and second speed gear, which should be .003" to .008". *End play in excess of .008" will permit gear "jump out."*
6. After mainshaft is properly positioned, select a snap ring that will be a snug fit at the rear bearing.

GEARSHIFT, ADJUST

1. Remove screws that retain upper boot and retaining ring to floor pan.
2. Remove retaining ring, then slide boot up on gearshift lever far enough to expose the shift mechanism.
3. Disconnect low-reverse shift rod and disengage rod from lever.
4. Disconnect 2-3 shift rod and disengage rod from lever.
5. Place transmission shift levers in neutral, Fig. 2.
6. Slide a suitable tool over cross-over pin on 2-3 lever side. This will position cross-over pin so that shift levers are locked in neutral position.
7. Preset length of low-reverse shift rod by loosening lock nut on end of rod, which is threaded through swivel block. Turn swivel block either in or out to properly position hand lever and shift levers in neutral position. *Correct neutral position is where shift levers are in a direct vertical position with floor pan.*
8. After correct vertical position of both levers have been obtained, secure low-reverse rod to its lever.
9. Loosen clamp nut holding 2-3 shift rod in swivel block.
10. Slide swivel block either to front or rear on rod until stub shaft on block can be inserted into its lever. Install washer and clip.
11. With levers on transmission in neutral, tighten clamp nut that holds 2-3 rod in swivel.
12. Complete assembly and check shift in all gears. Cross-over action should be smooth, and shifting into gears should be crisp without binding.

TORQUEFLITE 6

A detailed service procedure on this transmission is given in the *Automatic Transmission Section* of this manual.

Fig. 2 Gearshift linkage

Transmission, Replace

1. Disconnect battery ground cable.
2. Depress "L" button to position control cable for removal from transmission.
3. Remove starting motor.
4. Raise vehicle on a hoist or support with stands.
5. Remove cover plate from in front of converter to provide access to converter drain plugs and mounting bolts.
6. Drain converter and transmission.
7. Remove neutral starter switch.
8. Remove cable adjusting wheel lock screw at transmission.
9. Insert screwdriver through neutral starting switch opening. Push screwdriver gently against upper projecting portion of cable lock spring, and pull cable out of transmission.
10. Loosen clamp screw and remove throttle link and lever from throttle shaft.
11. Disconnect oil cooler lines at transmission and remove oil filler tube.
12. Remove speedometer driven gear and sleeve.
13. Loosen transmission parking brake cable clamp bolt where cable enters cover. Remove housing cover lower plug. Insert screwdriver through hole, then gently exert pressure against projecting portion of cable lock spring and withdraw brake cable.
14. Disconnect front universal joint and secure out of the way.
15. Remove nut securing extension housing insulator to crossmember.
16. Raise engine slightly.
17. Disconnect rear wheel brake cable from lever and crossmember. Then remove crossmember.
18. Support transmission with a jack.
19. Mark converter and flex driving plate so they can be assembled in the same relative position. Remove converter to flex plate screws.
20. Attach a small "C" clamp to edge of bell housing to hold converter in place during transmission removal.
21. Remove bell housing retaining bolts.
22. Carefully work transmission rearward off engine block dowels and to disengage converter hub from end of crankshaft.
23. Lower transmission jack and remove transmission and converter.
24. Reverse above procedure to install the assembly.

THROTTLE LINKAGE

1962 Manual Trans.

1. Disconnect choke at carburetor or block choke valve open. Open throttle slightly to release fast idle cam, then close throttle.
2. Disconnect top end of accelerator pedal rod, Fig. 3. Adjust length of this rod to provide a pedal angle of 111° to 113°. Reinstall top end of rod.
3. Connect or unblock choke.

1962 Automatic Trans.

1. Referring to Fig. 3, disconnect ball joint at upper end of bellcrank-to-torque shaft rod.
2. Disconnect choke at carburetor or block choke valve open. Open throttle slightly to release fast idle cam, then close throttle.
3. With lock nut loose in transmission rod, insert a 3/16" diameter rod approximately 4 inches long through holes in bellcrank bracket and lever assembly.
4. Move transmission lever forward

against the stop and tighten transmission lock nut.

5. Disconnect top end of accelerator pedal rod. Adjust length of this rod to provide a pedal angle of 111° to 113°. Reinstall top end of rod.
6. Remove 3/16″ gauge rod and adjust length of transmission bellcrank-to-torque shaft rod by means of the screw adjustment at the top end. The correct rod length allows the ball socket to line up with the ball end when the rod is held upward against the transmission stop.
7. Install ball socket. Connect or unblock choke.

1960-61

1. With engine at operating temperature and carburetor off the fast idle cam, adjust idle speed to 500 rpm.
2. Loosen lock nut and move transmission throttle control lever forward until it stops. Then tighten lock nut securely.
3. Adjust a spirit level protractor to 115 degrees; then place protractor lengthwise on flat face of accelerator pedal.
4. With car on level floor, disconnect accelerator pedal rod and adjust length of rod to center the bubble in spirit level. After correct pedal angle is obtained, reconnect pedal rod.

Fig. 3 Throttle linkage. 1962 Lancer and Valiant with manual or automatic transmission

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE REPAIRS

The rear axle is an integral type design with the axle housing and differential carrier housing integrated into one component. Access to the differential carrier is obtained by removal of housing cover, Fig. 1.

Differential bearing preload is adjusted by a spacer located between the end of the differential side bearings and the housing.

Drive pinion depth is adjusted by a spacer located back of the rear pinion bearing.

Pinion bearing preload is adjusted by a spacer located between the front pinion bearing and the shoulder on the pinion shaft.

Cross and roller universal joint

Disassemble

1. Remove rear axle assembly from car.
2. Drain lubricant and remove cover.
3. Remove pinion yoke.
4. Remove pinion oil seal.
5. Check ring gear and differential case runout by placing a dial indicator against machined surface on back face of ring gear. Rotate ring gear slowly and check reading. If runout exceeds .005″, check case after ring gear is removed to determine if runout is in the case or in drive gear, as described later on.
6. If differential bearing caps have no identifying marks, punchmark the caps and housing to identify right and left caps on reassembly. Then remove caps.
7. Install spreader tool and dial indicator as shown in Fig. 2 and check ring gear runout. Tighten spreader and spread housing .012-015″. *Do not spread housing in excess of .020″ as permanent distortion of housing may result.*
8. Remove dial indicator and pry differential case out of housing with a pry bar, Fig. 3.
9. Remove drive pinion and bearings.
10. Remove ring gear.
11. If ring gear runout was excessive when checked in Step 5, check the case to determine if the runout is in the gear or the case.
12. Reinstall differential case with spacers in housing. Remove spreader

Fig. 1 Rear axle differential and carrier

and install bearing caps and torque to 45 ft. lbs.

13. Mount dial indicator as shown in Fig. 4. Rotate case several times to seat bearings. Then turn case slowly and check indicator for runout. If the same reading is obtained as made with the ring gear and case, runout is in the case and not the drive gear.
14. Remove bearing caps, install spreader and spread housing .012-.015″.
15. Remove differential case, then the spreader.
16. Remove differential bearings if necessary.
17. Drive out lock pin which secures differential pinion shaft in case.
18. Drive out pinion shaft and remove pinions, side gears and thrust washers.
19. Remove rear pinion bearing and spacer from shaft. If bearing cups are to be removed, drive out with a brass drift.
20. Wash all parts and check bearings, cups, gears and thrust washers for nicks, burrs or damage and replace as required.

Assemble

1. Assemble differential by placing side gears and thrust washers into place. Mesh pinions with side gears. Install pinion thrust washers and rotate gears until pinions line up with pinion shaft holes. Install pinion shaft and lock pin.
2. Install ring gear and tighten bolts to 35 ft. lbs.
3. Install differential bearings.

Differential Bearing Preload, Adjust

1. Install spreader and spread case .012-.015″. Position differential bearing cups over bearings and install differential in carrier housing. Then remove spreader.
2. Measure original spacer thickness. Select a spacer approximately .012″ thinner for end play trial spacer. Install spacers between bearing cups and housing. Force differential to one side. On the other side, see how much shim stock will go between bearing cup and housing with a slight drag.
3. Measure total thickness of spacers plus feeler gauge stock to give the thickness of spacers needed to bring clearance to zero, Fig. 5. Then add .003″ to .006″ to the total for correct preload. Install spreader and remove differential from housing; then remove spreader.

Drive Pinion Depth

1. Look at the end of the new pinion to see if it has a plus or minus

Ball and trunion universal joint

Fig. 2 Checking ring gear runout, using a spread tool and dial indicator

Fig. 4 Checking differential case runout with dial indicator

Fig. 5 Checking differential end play

marking on it. Then if the new pinion has a different marking than the old pinion, use a thicker or thinner spacer by the amount that the new pinion differs from the old. Spacers are available in thickness steps of .002″ from .074″ to .106″. Pinions are marked 0, +1, +2, +3, —1, —2, —3.

2. Install pinion into carrier.
3. Install selected spacer on shaft with chamfer on spacer toward pinion gear.
4. Install front pinion bearing. Install yoke (not oil seal) and torque nut to 220 ft. lbs.
5. With pinion in vertical position, rotate pinion several times to seat bearings. Then, using an inch pound torque wrench, check rotating torque which should be 15-25 inch lbs. If not enough preload is present, install a thinner spacer; if too much, install a thicker spacer.
6. After correct spacer has been installed, install pinion shaft oil seal. Then install yoke and torque nut 220 ft. lbs.
7. Install spreader and spread housing .012-.015″.
8. With differential side bearing cups over bearings and spacers in position, install differential into housing, Fig. 6. Loosen spreader; but as spreader is released, make sure that some backlash is present when spreader is fully released. If backlash disappears before spreader is fully released, install a thinner spacer on the ring gear side and an equally thicker spacer on the opposite side. Install bearing caps, aligning locating punchmarks, and tighten cap bolts to 45 ft. lbs.
9. Check backlash between ring gear and pinion at least in four points, Fig. 7. The backlash at the lowest point must be from .004-006″. There can be no more than .003″ difference from the lowest backlash point to the highest.
10. Install housing cover.

Axle Shaft, Replace

1. With wheel removed, remove clips holding brake drum on wheel studs and remove brake drum.
2. Disconnect brake lines at wheel cylinders.
3. Using access hole in axle flange, remove retainer nuts from end of housing.
4. Attach a suitable puller and remove axle shaft and brake assembly from housing. Remove brake assembly from axle shaft with care, to avoid damaging the shaft in the seal contact area.
5. Remove axle shaft oil seal from housing.
6. With a suitable tool, remove the bearing from the shaft. *Removal of the bearings makes them unfit for further use.*

Fig. 6 Installing differential assembly

Fig. 3 Prying differential out of housing

Fig. 7 Checking ring gear backlash

7. Reverse removal procedure to install.

BRAKE MASTER CYLINDER, REPLACE

To remove the master cylinder, disconnect the master cylinder push rod from brake pedal. Disconnect brake line and stop light wires from cylinder. Remove attaching nuts and remove cylinder from car.

On cars with power brakes, the master cylinder push rod is a part of the vacuum brake and is not retained in the master cylinder piston. On removing the cylinder from the booster, the piston and cups may drop out of the cylinder. To prevent this proceed as follows:

1. Clean dirt away from master cylinder cover and remove cover.
2. Lightly depress brake pedal and insert a 1/8" wire or drill through the large hole in the brake reservoir to retain the piston in the cylinder.

POWER BRAKE UNIT

1. Disconnect vacuum line from vacuum cylinder.
2. Disconnect hydraulic brake line from master cylinder.
3. Disconnect wires from stop light switch.
4. Under instrument panel, disconnect push rod from pedal linkage.
5. Remove attaching nuts from brake unit mounting bracket and remove unit from car.

Front End & Steering Section

WHEEL ALIGNMENT

Before checking and adjusting wheel alignment, make sure the front wheel bearings are properly adjusted and that the front suspension height is correct. These adjustments are given further on.

Camber and Caster

Camber and caster adjustments are accomplished by means of the upper control arm attaching bolt and cam assemblies, Fig. 1.

To adjust caster and camber, carefully loosen the upper control arm adjusting bolt nuts while holding the bolts to prevent turning.

Adjustment of caster through camber readings is possible because of the consistent relation between caster change and camber change when either the front or rear cam bolt at each control arm is individually rotated.

Turning one bolt affects caster more than camber. Turning both bolts an equal amount in the same direction affects camber directly, and caster indirectly. Turning the cams an equal amount in opposite directions will change caster with little change in camber, depending on the relative position of the cams.

By bringing caster within specifications by turning one bolt at a time, then by turning both bolts an equal amount to bring camber to the preferred reading, the caster will usually be brought close to the preferred setting.

After both caster and camber readings are correct, tighten the nuts to a torque of 65 ft lb while holding the bolts from turning.

Always recheck the settings after tightening the nuts since the bolts may have turned slightly during the tightening process.

Service Note

The direction the cam is turned initially depends upon the position of the high spot of the cam. The procedure is to turn the eccentric in either direction until the desired movement takes place. If you continue turning past the high spot of the cam the movement will start to reverse. In other words, the high spot is the limit of adjustment in either direction.

Toe-In Adjustment, 1960-61

Take toe-in readings with front wheels in straight ahead position. When necessary to adjust, loosen the clamps at each end of both tie rod adjusting tubes, Fig. 2.

Adjust toe-in by turning the tie rod tube which will "center" the steering wheel spokes. If the steering wheel was centered, make the toe-in adjustment by turning both tubes an equal amount. Before tightening the clamps, turn tie rod so ball sockets are either against the front or back sides of studs. Torque bolts to 15 ft lb.

1962

With the front wheels in straight ahead position, loosen the clamps at each end of both adjusting tubes. Adjust toe-in by turning the tie rod sleeve which will "center" the steering wheel spokes. If the steering wheel was centered, make the toe-in adjustment by turning both sleeves an equal amount. Position the clamps so they are on the bottom and tighten bolts to 15 ft. lbs.

RIDING HEIGHT

Before taking measurements, grasp the bumpers at the center (rear bumper first) and jounce the car up and down several times. Jounce the car at the front bumper the same number of times and release the bumper at the same point in the cycle each time.

1. Measure from the ball joint to the floor (measurement "A"), and from the control arm torsion bar spring anchor housing to the floor (measurement "B").
2. Subtract "A" from "B". The distance should be 1 3/4" on 1960-61 and 1 7/8 on 1962 (plus or minus 1/8").
3. Measure the other side in the same manner.
4. Adjust by turning the torsion bar anchor adjusting nut *clockwise to increase* the height and *counterclockwise to decrease* the height. The difference from side-to-side should not exceed 1/8".
5. After adjusting, jounce the car and recheck the measurements on both sides, even if only one side may have been adjusted.

WHEEL BEARINGS

1. To adjust bearings, tighten wheel bearing adjusting nut to 70 inch lbs while rotating the wheel.
2. Position nut lock on nut with one pair of slots in line with cotter pin hole.
3. Back off lock and adjusting nut 1 1/2 slots (cotter pin hole will be covered).
4. Remove lock and re-position it so the cotter pin can be inserted. *Do not move adjusting nut.* Install cotter pin.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight.

Although the car company publishes no specific recommendations, a reliable method is to jack up under the lower control arm near the outer end. Then grasp the tire at the top and bottom and move it in and out. If wheel movement or play in excess of 1/4" is evident, replace the joint or joints as required.

Fig. 1 Exploded view of front suspension

ALL ARMS AND LINKS SWING THROUGH SIMILAR ARCS
MINIMIZING EFFORT THROUGHOUT THE ENTIRE STEERING RANGE

Fig. 2 Steering linkage

FRONT END REPAIRS

Lower Control Arm Strut

1. Remove mounting bolts.
2. Remove nut and bushing retainer from forward end of strut at cross-member.
3. Slide strut and inner bushing retainer from bushing.
4. Pry bushing from "K" member with screwdriver.

Installation

1. Dip new bushing in water and with tapered portion toward rear of car, install in "K" member, using a twisting motion until groove in bushing seats properly with support member.
2. With cupped side out, slide bushing retainer over threaded end of strut. Push strut through bushing in cross-member, position outer bushing over end of strut (cupped side in) and install nut *finger tight only.*
3. Install strut-to-control arm bolts and torque nuts to 100 ft lb.
4. Lower car to floor and jounce car to permit bushing to assume its normal position on strut.
5. Tighten nut on forward end of strut to 40 ft lb.

Torsion Bar Springs

The torsion bars are not interchangeable from side to side. The bars are

Fig. 3 Exploded view of manual steering gear

marked as either right or left by an "R" or an "L" stamped on one end of the bars. *Do not lift by the front suspension control arms for this operation.*

1. If car is to be raised on a hoist, make sure it is lifted on the body so that the front suspension is in full rebound (under no load). If the car is to be raised on a jack, place jack under center of "K" member and raise car off floor so front suspension is under no load.
2. Release load from torsion bar by backing off anchor adjusting nuts. Remove adjusting nut and swivel bolt.
3. Remove strut.
4. Remove lock ring from rear of torsion bar rear anchor.
5. To facilitate removal of torsion bars, install Tool C-3728 on the torsion bar and move bar rearward by holding tool firmly and hitting pad on tool with a hammer. *Do not apply heat to front and rear anchors. The surface of the torsion bar must not be scratched or marred in any manner.*
6. Remove tool and slide rear anchor balloon type seal off front end of torsion bar.
7. Remove torsion bar by sliding it rearward and out through rear anchor.

Installation

1. Clean hex openings in anchors and from hex ends of torsion bar springs.
2. Insert torsion bar through rear anchor.
3. Slide rear anchor balloon type seal over torsion bar, with large cupped side of seal facing rearward.
4. Coat both ends of torsion bar with multi-purpose grease.
5. When inserting torsion bar into anchor in lower control arm, *position adjusting arm approximately 60 degrees below the plane of the control arm, otherwise adjustment of the front suspension to the correct height will not be possible.*
6. Install lock ring in rear anchor, then move torsion bar rearward until bar contacts lock ring.
7. Position swivel bolt on control arm and hold it in place while adjusting nut and seat. Tighten adjusting nut about 10 turns before lowering car to floor.
8. Pack annular opening of rear anchor with multi-purpose grease. Slide rear anchor balloon type seal into position over rear anchor until lip of seal indexes with the groove.
9. Install the strut.
10. Lower car to floor and adjust front suspension height as required.

Upper Ball Joints

1. Place jack under lower control arm as close to wheel as possible. Raise wheel off floor and remove from car.
2. Remove ball joint stud nut.
3. Place spreader tool C-3711 or equivalent down on flat section of lower control arm. Turn threaded portion of tool, locking it securely against upper stud. Spread tool enough to place upper stud under pressure, then strike steering knuckle sharply with a hammer to loosen stud.
4. Remove tool and disengage ball joint from knuckle. Remove ball joint balloon seal by prying metal retainer edge loose with a screwdriver.
5. Unscrew ball joint from upper control arm.

Installation—When installing a new ball joint, it is important that the ball joint threads engage those of the control arm squarely. Balloon type grease seals should always be replaced once they have been removed.

Screw ball joint into control arm and tighten until ball joint housing is seated on control arm. Tighten to a minimum of 125 ft lb. Tighten ball joint in steering knuckle to a torque of 55 ft lb.

When assembly is completed, lubricate ball joint. Install wheel.

Lower Ball Joint

1. Place jack under lower control arm and raise car.
2. Remove wheel and brake drum.
3. Disconnect tie rod from steering arm. Remove nut, then loosen stud by striking the arm sharply while "backing up" with a heavier hammer.
4. Remove brake backing plate and support it so no strain is put on brake hose.
5. Disconnect ball joint from lower control arm and remove knuckle arm.
6. Place assembly in vise and remove balloon seal and ball joint.

Installation

1. Screw ball joint into steering arm as far as possible by hand. Then tighten ball joint housing to a minimum of 300 ft lb until ball joint is seated in steering knckle arm.
2. Slide a new balloon seal into position, using extreme care not to pinch the rubber or deform metal retainer of seal.
3. Lubricant ball joint.
4. Install steering knuckle arm on brake support plate and connect ball joint to lower control arm, and tie rod end to steering knuckle arm. Tighten ball joint stud nut to 90 ft. lb. and tie rod end to 50 ft. lb.
5. Install drum and wheel and adjust front wheel bearings.

Lower Control Arm

1. Place jack under "K" member and raise car so that both wheels are clear of floor.
2. Disconnect strut from lower control arm.
3. Remove torsion bar.
4. Remove wheel and brake drum.
5. Disconnect shock absorber at lower control arm bracket; then push shock absorber up out of the way.
6. Disconnect lower ball joint stud from lower control arm.
7. Support brake support plate so as not to put strain on brake hose.
8. Remove nut attaching lower control arm shaft to "K" member. Reinstall nut until flush with end of shaft to protect the threads.
9. Using hammer and brass drift, loosen shaft (tapered fit) and remove nut.
10. Slide lower control arm and shaft out from rear of crossmember.
11. Remove old and install new bushings as required.

Installation

1. Position shaft and control arm in the "K" member in approximate operating position. Install washer and nut finger tight only.
2. Connect ball joint to steering knuckle and tighten nut to 55 ft. lb.
3. Connect shock absorber and tighten nut to 55 ft. lb.
4. Install torsion bar, strut, and wheel and drum assembly.
5. Lower car to floor. Then jounce car and set front suspension heights.
6. Tighten lower control arm shaft nut to 160 ft. lb.
7. Check and adjust front suspension as necessary.

Upper Control Arms

The upper control arm support mounting brackets are welded to the shock absorber tower and to the body horizontals (side rails).

1. Place jack under lower control arm as close to wheel as possible.
2. Raise car and remove wheel.
3. Remove upper ball joint stud from steering knuckle.
4. Remove nuts, cams and cam bolts. Lift control arm away from support.
5. Remove balloon type seal by prying retainer loose with screwdriver.
6. Remove old and install new bushings as required.

Installation

1. Slide control arm into position and install cam bolts, cams and nuts. Tighten nuts in preparation for final adjustment.
2. Slide upper ball joint stud into position in steering knuckle. Install washer and nut and tighten to 55 ft. lb.
3. Install wheel and remove jack.
4. Check and adjust car height and alignment, then tighten control arm cam bolt nuts to 65 ft. lb.

HORN SOUNDER & STEERING WHEEL

1. Disconnect battery ground cable.
2. Rotate horn button ¼ turn counterclockwise and remove button.
3. Remove three screws and bushings from button base and lift out base or horn ring.
4. Disconnect wire from horn switch and remove switch.
5. Remove wheel nut, attach puller and remove steering wheel.

MANUAL STEERING GEAR

Replace

1. Unscrew sector shaft arm retaining nut and remove arm with a puller.
2. Remove bolts attaching gear to frame.
3. Remove bolt from coupling clamp at upper end of steering gear worm shaft.
4. While supporting the gear, tap the coupling assembly upward with a mallet until it is free from worm shaft splines. Then lift out steering gear.

MANUAL STEERING GEAR REPAIRS

A worm and recirculating ball type steering gear is used with the manual steering gear system, Fig. 3. The steering worm shaft is a "stub" type and is connected to the steering shaft with a universal joint type coupling. The worm shaft is supported on each end by ball type thrust bearings. The sector shaft rotates in two needle bearings in the steering housing and a needle bearing in the housing cover.

Two adjustments are required: worm bearing pre-load, and ball nut and sector gear mesh. These adjustments must be made carefully and in the order given to ensure satisfactory results.

Worm Bearing Pre-load

1. Disconnect steering gear arm from sector shaft.
2. Loosen sector shaft adjusting screw lock nut and back out adjusting screw approximately two turns. This relieves the load imposed by the closely meshed ball nut and sector gear teeth.
3. Turn steering wheel two complete turns from straight-ahead position. *Do not turn steering wheel hard against stops in gear when steering gear arm is disconnected as internal damage might result.*
4. Hook a spring scale to the steering wheel and rotate the wheel at least one turn (toward straight-ahead position) with the scale. The pull required to keep the wheel moving should be between ¼ and ¾ lb. If the reading is not within these limits, adjustment of the worm bearing pre-load is necessary.
5. To adjust the pre-load, loosen the lock nut on the large adjuster nut which threads into the housing. Turn the adjuster clockwise to increase pre-load or counter-clockwise to decrease the pre-load.

Ball Nut and Sector Gear Mesh

The sector shaft adjusting screw, located in the housing cover, raises or lowers the shaft to provide the proper mesh load between the tapered teeth of the sector gear and tapered teeth of the ball nut. This adjustment is made only after the proper worm bearing pre-load has been obtained.

1. Turn steering wheel gently from one stop all the way to the other, carefully counting the number of turns. Then turn the wheel back exactly half way, to the center position.
2. Turn the sector shaft adjusting screw clockwise to take out all lash between the gear teeth, then tighten the adjusting screw lock nut.
3. Turn the steering wheel about ¼ turn away from center and, using a spring scale, check the pull required to move the wheel through the high spot (center) position. The scale reading should be between 1 and 1⅝ lb. This represents the total of the worm bearing pre-load and the gear mesh load. Readjust, if necessary to obtain proper pull.
4. After the adjustments have been completed, align front wheels in the straight-ahead position. Then install steering arm on sector shaft and tighten retaining nut to 120-130 ft lb.

POWER STEERING

The power steering gear used is the Constant Control type used on other Chrysler cars but built on a smaller scale. However, servicing the gear is essentially the same.

To remove the steering gear, proceed as follows:

1. Unscrew gear shaft arm retaining nut and remove arm with a puller.
2. Disconnect hydraulic lines from steering gear valve.
3. Remove bolts attaching gear to frame.
4. Remove bolt from coupling clamp at upper end of steering gear worm shaft.
5. While supporting gear, tap coupling assembly upward with a mallet until it is free from worm shaft splines. Then lift gear out of car.

Instruments, Radio & Windshield Wiper

INSTRUMENT CLUSTER

1961 Lancer

1. Remove heater switch trim plate.
2. Remove transmission push button trim plate.
3. Remove steering wheel.
4. Loosen (do not remove) steering column jacket tube clamp and steering jacket to lower instrument panel screws.
5. Disconnect speedometer cable at speedometer.
6. Unfasten and pull instrument cluster and casting from panel housing.
7. Separate cluster panel from panel cluster casting.
8. Disconnect all wires and remove instrument cluster and remove instrument bezel from cluster base.
9. Remove all gauges.
10. Remove speedometer from cluster base.

1962 Lancer & Valiant

1. Remove battery ground cable.
2. Remove headlamp and wiper switch knobs by inserting a screwdriver blade in slot of switch knob to depress retaining spring while pulling knob outward.
3. After removing four screws from face of cluster bezel, pull bezel outward and tilt it out from top edge. *The speedometer can be removed after removing the bezel by removing the 3 screws attaching speedometer to cluster base, and disconnecting speedometer cable.*
4. Remove 8 attaching screws and carefully lift out printed circuit and instruments.
5. Remove mutli-connector from printed circuit pins on connector while pushing against master locator.
6. Disconnect wires from ammeter.
7. The instrument cluster can then be removed completely.

1960-61 Valiant

1. Disconnect battery ground cable.
2. Remove headlamp switch knob.
3. Unfasten and pull top of instrument cluster forward.
4. Disconnect speedometer cable from speedometer and electrical connections.
5. Remove instrument cluster.
6. Remove speedometer from cluster.

RADIO

1960-62 Lancer & Valiant

1. Disconnect battery ground cable.
2. Remove radio speaker grille.
3. Disconnect "A" antenna lead and speaker leads.
4. Remove nuts from radio mounting studs.
5. Remove radio opening cover plate.
6. Unfasten radio from support housing.
7. Remove radio through opening between radio support and speaker.

WINDSHIELD WIPER

1962 Lancer & Valiant

1. Remove radio, speaker grille and speaker.
2. Unfasten wiper motor bracket from cowl panel and instrument panel brace.
3. Disconnect wires at wiper motor.
4. Disconnect links at pivot cranks. Clips are removed by lifting top tab and sliding it sideways out of engagement with groove in pivot crank pin. The right pivot may be reached through glove box opening.
5. Tip wiper motor and bracket on its side and remove left link.
6. Remove right defroster tube, the pencil brace between instrument panel reinforcement and wiper motor mounting.
7. Remove motor and bracket through speaker opening.

1961 Lancer

1. Remove heater switch trim plate.
2. Remove transmission push button trim plate.
3. Remove steering wheel.
4. Loosen (do not remove) steering column jacket tube clamp and steering jacket to lower instrument panel screws.
5. Disconnect speedometer cable at speedometer.
6. Unfasten and pull instrument cluster and casting from panel housing.
7. Separate cluster panel from panel cluster casting.
8. Disconnect all electrical connections and remove instrument cluster.
9. Remove radio speaker grille and speaker.
10. Unfasten and remove wiper motor through instrument panel opening.

1960-61 Valiant

1. Disconnect battery cable.
2. Remove glove compartment.
3. Pry radio speaker grille away from instrument panel.
4. Unfasten and lower radio speaker to gain access to wiper motor bracket.
5. Disconnect wires to wiper motor.
6. Remove headlamp switch pull knob.
7. Unfasten and pull top of instrument cluster forward to gain access to wiper pivot on left side.
8. Disconnect speedometer cable and wiper motor wires at panel switch.
9. Disconnect links at pivot cranks.
10. Slide wiper with links far enough toward left so that right hand link will clear glove compartment opening and remove wiper bracket with wiper and links as an assembly, being careful not to bend links.

Engine Section

ENGINE, REPLACE

In addition to the usual items such as fuel lines, linkage and radiator hoses, the following operations must be performed:

1. Remove hood, radiator and air cleaner.
2. On 1955-57 models, remove defroster blower motor and on 1953-55, the oil filter.
3. Remove power steering pump and starter.
4. Disconnect exhaust pipes from manifolds.
5. On 1956-57 models, remove radiator splash shield and radio speaker.
6. Support transmission with a suitable jack.
7. Unfasten engine mountings and attach lifting rig to engine.
8. Remove bell housing to engine attaching bolts and carefully lift engine out of chassis. *Be sure to support transmission with front end tilted up to prevent converter from falling out.*

CYLINDER HEADS

1955-57

1. Disconnect throttle linkage at carburetor and remove capscrews holding linkage brackets to cylinder block and intake manifold.
2. Disconnect fuel and vacuum lines from fuel pump, intake manifold and carburetor and remove lines and fuel pump.
3. Remove vacuum line from carburetor and distributor. Disconnect high tension lead and primary ignition wire from coil and take off coil.
4. Remove distributor cap and wiring harness brackets and take off these parts as a unit.
5. Disconnect automatic choke arm from carburetor and remove choke assembly.
6. Loosen heater tube connections at intake manifold and carburetor. Take off carburetor and pull heater tube straight up from manifold.
7. Remove front exhaust cross-over pipe and both exhaust manifolds. *Caution*—Do not scratch surfaces of exhaust ports since gaskets are not used at these locations.
8. Remove oil filler cap and pipe and oil dipstick and tube. If the tube is tight, tap it lightly on the welded bracket with a hammer.
9. Remove rocker arm covers and gaskets by removing two acorn nuts and lockwashers.
10. Remove distributor retaining bracket and pull distributor gently from block. Notice the distance the rotor turns as the distributor is removed. This will be very helpful when distributor is reinstalled as the helical gears turn the shaft.
11. Remove intake manifolds and gaskets. When this operation is done, make sure the cover is cleaned first so dirt does not fall into the push rod chamber.
12. Loosen push rod adjusting nuts and screws to relieve tension on push rods.
13. Remove capscrews and nuts holding rocker arm assemblies to cylinder heads.
14. Remove oil overflow pipe from end support at front on right bank and at rear on left bank.
15. Remove rocker arm assemblies, Fig. 1, and lift out push rods. Retain push rods in correct order to assure proper assembly.
16. Remove two end cylinder head capscrews and install pilot studs, Fig. 2.

Note—It is strongly recommended that the cylinder head holding fixture shown in Fig. 3 be used as it has been designed so all work operations may be performed with the fixture in place. Thus, the machined surfaces are being protected from being scratched or marred which would require extensive repair work to prevent a gasket leak.

17. Install the fixture as shown in Fig. 2, using intake manifold bolts. Remove remaining cylinder head capscrews and lift the heads off the two locating dowels and pilot studs.
18. Install the heads in the reverse order of removal and tighten the hold-down bolts in the sequence shown in Fig. 3 and to the torque values given in the *Engine Tightening* chart.

Fig. 1 Removing rocker arm assembly. 1955-57

Fig. 3 Cylinder head tightening

1958-62 engine. Note wedge-shaped combustion chamber formed in block and that underside of cylinder head is flat

1958-62

1. Drain cooling system.
2. Remove rocker arms and push rods.
3. Remove intake manifold.
4. Remove ignition coil from the left cylinder if that particular head is being removed.
5. Unfasten exhaust pipe from manifold.
6. Unfasten and remove cylinder head and exhaust manifold as a unit. *The exhaust manifolds should not be*

Engine lubrication. 1958-62

Engine lubrication. 1955-57

Fig. 4 Adjusting valve clearance for zero lash. 2½ turns on 1955-57

separated from the cylinder heads unless the head is to be replaced or the valves are to be ground.

Installation

Install the cylinder heads in the reverse order of removal. Tighten the heads in the sequence shown in Fig. 3 and to the torque given in the *Engine Tightening Chart.*

1958-62 Left Bank . . . . . E-I-E-I-E-I-E-I

VALVES, ADJUST

1955-57

Take off the distributor cap and turn the engine until the distributor rotor is at the firing position for No. 1 cylinder. When this is done, the following valves will be fully closed and, therefore, can be adjusted:

No. 1 intake and exhaust.
No. 2 intake and exhaust.
No. 5 intake and exhaust.
No. 4 exhaust; No. 7 intake.

After setting up the above valves, turn the engine so the distributor rotor is at the firing position for No. 6 cylinder. Then the rest of the valves can be adjusted. These are:

No. 3 intake and exhaust.
No. 6 intake and exhaust.
No. 8 intake and exhaust.
No. 4 intake; No. 7 exhaust.

To make the adjustment, turn the adjusting screw clockwise while moving the push rod up and down until all slack is removed (do not force the hydraulic plunger down into the lifter body). After removing all slack, turn the adjusting screw an additional 2½ turns, Fig. 4. Hold the adjusting screw and tighten the lock nut. If any lifter is noisy during subsequent operation, the adjustment may be varied by turning the adjusting screw an additional ½ turn from the 2½ setting.

ROCKER ARMS

Sludge and gum formation in rocker arms and shafts, Figs. 5 and 6, will restrict the normal flow of oil to the rocker arms and valves. Each time the assemblies are removed (see *Cylinder Head*) they should be disassembled and thoroughly cleaned.

Remove the support bracket bolts, cotter pins, washers, springs, support brackets, and shafts. Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Inspect the shafts for wear. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When the assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves. The oil overflow pipe hole in the shaft should be seen through the center hole of the front support on the right bank and the rear support on the left bank. If the hole cannot be seen, turn the shaft until the holes line up.

Check each push rod for a bent or damaged condition. If bent more than

Fig. 5 Layout of rocker arm assembly. 1955-57

.020″ when checked with an indicator, replace the rod; do not attempt to straighten a bent rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

VALVES, REMOVE

With the cylinder head removed as outlined previously, use a suitable valve spring compressor, Fig. 7, to compress each spring. Remove the valve locks and sleeve, tapping the sleeve with a soft hammer if necessary. Remove the sleeve from the valve stem and release the pressure on the spring. Remove the spring compressor and lift off the valve retainer sleeve, retainer, spring and valve. Repeat for the remaining valves. Keep the valves and related parts together so they may be installed in their respective positions if found in satisfactory condition.

VALVE GUIDES

Valve guides in these engines are an integral part of the head and, therefore, cannot be removed. For service, guides can be reamed oversize to accommodate one of three service valves with oversize stems (.003″, .015″ and .030″).

Check the valve stem clearance of each valve (after cleaning) in its respective valve guide. If the clearance exceeds the service limits of .004″ on the intake or .005″ on the exhaust, ream the valve guides to accommodate the next oversize diameter valve.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

Fig. 7 Showing use of cylinder head holding fixture and valve spring compressor

Fig. 6 Rocker arm assembly 1958-62 engines

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 7A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}$″ to $\frac{5}{64}$″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 8, and according to the specifications given in the *Valve Data Chart.* If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$″, otherwise the valve must be replaced, Fig. 9.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

1958-62 Service Note

Whenever a complaint of hydraulic lifter noise is encountered, and also after performing a valve grind job or replacing a cylinder head the hydraulic lifters

Fig. 7A Checking valve spring installed height

Fig. 8 Special fixture for checking valve spring pressure. All models

should be collapsed and the valve stem to rocker arm clearance checked. Each lifter should be checked individually to guard against differences in machining or wear variables.

Valve stem to rocker arm clearance should check between .078″ and .218″. If it does the existing push rod should be retained. If the actual measured clearance is less than .078″, a .060″ *shorter* push rod (color coded white) should be installed. When the actual measured clearance is more than .218″, a .060″ *longer* push rod (color coded yellow) should be installed.

To check the clearance a special spanner-type tool is available to apply pressure on the rocker arm to bleed down the hydraulic lifter until the plunger is completely bottomed. Of course, checking must be done with lifter on heel of cam. If the special tool is not available, a stiff rod such as a socket extension and a length of wire can be used to collapse the lifter. Wire one end of the rod to the rocker arm as close to the valve stem as possible and apply pressure to the other end.

HYDRAULIC VALVE LIFTERS

The internal parts of each hydraulic valve lifter assembly are a matched set. If these are mixed, improper valve operation may result. Therefore, disassemble, inspect and test each assembly separately to prevent mixing the parts.

Figs. 10 and 11 illustrate the type of hydraulic lifter used. See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method of locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Press one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

To disassemble, first immerse the lifters in solvent and remove all traces of carbon and varnish. Remove the lock ring from the lifter body and disassemble as shown in the illustrations. Wash all parts in solvent and wipe dry with a lint-free cloth.

To assemble, hold the plunger inverted and assemble the valve disc, small spring, valve disc retainer and large spring on the plunger. Slip the body over the plunger, then install the push rod cup and lock ring in the body.

TIMING CASE COVER

1955-57

1. Drain cooling system.
2. Remove top radiator air deflector, hood latch support brackets, horns, radiator and hoses.
3. Disconnect generator wires, and water by-pass tube from water pump and outlet connection.
4. Remove fan blades.
5. Loosen generator adjusting bracket and take off fan belt.
6. Unfasten generator bracket from front cover and cylinder block and remove generator.
7. Remove seven cap screws which fasten water pump and heat deflection plate to front cover.

Fig. 9 Refaced valve requirements. Intake valves for 1958 have 30° angle

Fig. 10 Two designs of hydraulic valve lifters. 1955-57

8. Use a suitable puller to remove vibration damper.
9. Remove front cover and timing pointer by taking out five remaining cap screws.

1958-60

1. Remove the radiator.
2. Remove power steering pump and mounting bracket from engine.
3. Remove generator adjusting bracket and belt or belts.
4. Remove fuel pump.
5. Remove water pump.
6. Remove vibration damper with a suitable puller. Also spacer.
7. Unfasten timing chain cover from engine block and oil pan. *If oil pan gasket is broken or damaged during disassembly or assembly, remove the oil pan and install new gasket.*
8. Install a new cover oil seal if necessary and reinstall the cover in the reverse order of removal.

1961-62

1. Drain cooling system and disconnect water hoses. Remove radiator supply tank, thermostat and gasket.
2. Disconnect wires from coil, engine ground strap and battery ground cable at water pump.
3. Remove fan shield from radiator.
4. On air conditioned cars, loosen bracket bolts and push compressor inward toward engine and remove drive belt. Remove fan blade, fan and compressor drive pulley as a unit.
5. Remove generator splash shield and drive belts. Remove fan, spacer and mounting bolts from water pump as a unit.
6. Remove water pump.
7. Remove vibration damper.
8. Remove power steering pump.
9. Remove fuel pump. Then remove cup-type plug from top of cylinder front cover with a long punch.
10. Raise front of car and unfasten front cover from oil pan and cylinder block. Remove front cover. *If oil pan gasket is damaged during removal of front cover, it will be necessary to replace the gasket before installing front cover.*

Fig. 11 Hydraulic valve lifter disassembled. 1958-62

TIMING CHAIN

1955-57

Valve timing is set by aligning the two sprocket timing marks together on a center-to-center line between camshaft and crankshaft, Fig. 13.

1958-62

1. To remove the chain, first take off the timing chain cover as outlined previously.
2. Crank the engine until the timing mark on the camshaft sprocket is adjacent to the timing mark on the crankshaft sprocket, Fig. 13.
3. Remove cap screws, lock plate and fuel pump eccentric from front of camshaft.
4. Place a screwdriver behind the camshaft sprocket and carefully pry the sprocket and chain off the camshaft.
5. Reverse the foregoing procedure to install the chain, being sure to align the timing marks as shown in Fig. 13.

CAMSHAFT, REPLACE

1955-57

After removing the rocker arms, push rods, valve lifters and timing case cover, carefully withdraw the camshaft from the engine, being careful not to damage the camshaft bearings.

1958-62

If it is necessary to replace the camshaft only it may be accomplished without removing the engine from the chassis. But if the camshaft bearings are to be replaced the engine will have to be removed. To remove the camshaft, proceed as follows:

1. Remove the timing chain cover and chain as outlined previously.
2. Remove intake manifold.
3. Remove valve lifter cover.
4. Remove the hydraulic valve lifters and place them in a rack so they may be reinstalled in their respective bores. It may be necessary to remove the carbon from the top of the lifter bore before the lifters can be removed.
5. Remove grille.
6. Carefully slide camshaft out of engine.

CAMSHAFT BEARINGS

The camshaft is supported on five babbitt-lined, steel-backed bearing inserts. When necessary to replace these bearings, the engine will have to be removed from the vehicle and the plug at the rear of the cylinder block will have to be removed in order to utilize the special camshaft bearing removing and installing tools required to do this job. If properly installed, camshaft bearings require no reaming—nor should this type bearing be reamed or altered in any manner in an attempt to fit bearings.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the rods (original rods are marked) when removing them so they may be installed in their original cylinders.

Fig. 13 Valve timing

Fig. 14 Piston and rod assembly

PISTON & ROD, ASSEMBLE

If the old pistons are serviceable, make certain that they are installed on the rods from which they were removed. The assembly must be made as shown in Fig. 14.

PISTONS

If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston. See Fig. 15 for piston clearance specifications.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands. Pistons showing scuffed or scored skirts should be replaced by new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be discarded.

PISTON PINS

1955-57

It is recommended procedure to replace

Fig. 15 Piston clearance chart

piston pins whenever new piston rings are installed. Pins that have been relatively quiet when the old rings were in service may be noisy after new rings are installed. The pin should fit in the piston and rod by pushing it in with both thumbs with the parts at normal room temperature.

1958-62

Pins are a press fit and no snap rings are used to retain them in place.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. On 1949 and later engines, oversize rings of .020", .030" and .040" are available.

Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

ROD BEARINGS

These bearings are of the insert type, selectively fitted and requiring no reaming on installation. The bearings are available for service in standard and undersizes for use on journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Both main and rod bearings may be replaced by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing. Install the bearing and cap and tighten the nuts or bolts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then, loosen the nuts or bolts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope, Fig. 16. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousands of an inch.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance be-crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque* table.

CRANKSHAFT REAR OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding end of the seal with a sharp knife or razor blade.

Fig. 16 Checking bearing clearance with Plastigage. All models

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced, it is possible to do the job without removing the crankshaft as follows:

To remove the oil seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is being installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN, REPLACE

1955-57

To remove the pan, disconnect any steering linkage that seems necessary. Remove the external oil supply tube. Unfasten the oil pan attaching screws and lower the pan.

1958

1. Crank engine to bring No. 1 piston at approximately 14° BTDC to obtain clearance between crankshaft counterbalances.
2. Remove battery ground cable.
3. Remove oil level dipstick.
4. Raise car on hoist and drain oil pan.
5. Remove front engine support nuts.
6. Position jack under front edge of oil pan, using a block of wood between pan and jack.
7. Lower vehicle enough to raise front of engine about 2".
8. Place a block of wood (1" thick) between front engine support insulators and supports.
9. Raise car and remove jack.
10. Unfasten and lower oil pan to frame crossmember.
11. With pan resting on crossmember, remove lower and loosen upper oil pump inlet tube and screen retaining screws. This allows tube and screen to swing freely, permitting oil pan baffle clearance.
12. Oil pan may now be removed in a lowering forward motion.

1959-60

1. Crank engine to bring No. 1 piston at approximately 14 deg. BTDC to obtain clearance between crankshaft counterbalances (observe timing marks on damper).
2. Disconnect ground cable from battery.
3. Drain oil and remove dipstick.
4. Unfasten and lower pan to frame crossmember.
5. Remove oil pump inlet tube and screen retaining screws.
6. Remove pan.

1961-62

1. Remove hood and oil level dipstick.
2. Revolve engine to position No. 1 piston 15°BTDC for oil pan clearance purposes (refer to timing marks on vibration damper).
3. Set parking brake and raise car.
4. Drain oil pan.
5. Remove generator splash shield. Remove bolt securing automatic transmission oil inlet and outlet transfer line bracket to cylinder block.
6. To allow clearance for oil pan removal, remove engine front support retaining nut. Place a block of wood on a floor jack and position jack under front leading edge of oil pan. Raise engine about one inch and insert a ¾" block of wood between support insulators and underbody engine support pad. Then remove floor jack.
7. Unfasten and pull stabilizer arms downward to gain additional clearance.
8. Remove engine mounting bolts and bolt load spreaders. Free oil pan from block. Remove two mounting bolts securing oil pump pick-up tube and screen assembly to oil pump, and allow pump to drop into oil pan. Then remove oil pan.

OIL-VACUUM PUMP

1958-60

Vacuum booster pump and oil pump combination units, Fig. 17, are only used on engines equipped with vacuum windshield wipers. Electric windshield wiper equipped vehicles do not have the vacuum booster feature.

The oil pump section is serviced in the same manner as the pump without the vacuum pump. If the vacuum pump parts are damaged with score marks, wear or breakage, replace the complete vacuum pump.

Fig. 17 Oil and vacuum pump. 1958-60

OIL PUMP

1958 and 1961-62

To remove the pump, drop the oil pan as outlined above. Then remove the two bolts that attach the pump to the crankcase and remove pump, gasket and the intermediate shaft.

To disassemble, remove the pump cover plate, Fig. 18, and lift out the rotor and shaft. Scrape the stake marks that hold the relief valve in the pump housing until the retainer can be removed. Then remove the retainer, spring and relief valve from the pump housing. Inspect the pump as follows:

1. With all parts clean and dry, check the inside of the pump housing and the outer race and rotor for damage or excessive wear.
2. Check the mating surface of the pump cover for wear. If this surface is worn, scored or grooved, replace the cover.
3. Measure the clearance between the outer race and housing. This clearance should be .006-.012".
4. With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and housing. Measure the clearance between the straight edge and the rotor and outer race. Recommended limits are 0015-.004".
5. Check the drive shaft-to-housing

bearing clearance by measuring the O.D. of the shaft and the I.D. of the housing bearing. The recommended clearance limits are .0015-0029".

6. Inspect the relief valve spring for a collapsed or worn condition.
7. Check the relief valve piston for scores and free operation in the bore.

1955-57

The oil pump is mounted on the outside of the engine where it can be easily removed. When servicing the 1956-57 pump, refer to the procedure given for 1958 pump.

To disassemble the 1952-55 pump, remove cover. Tap cover gently with a soft hammer if stuck. Do not tap on the end of the drive shaft. Remove the gears from the body and take out the relief valve parts. Replace andy damaged parts and reassemble the pump.

RADIATOR, REPLACE

1955

Drain the radiator and remove upper and lower hoses. Remove the horns and place them behind the grille. Unfasten the hood latch support brackets, and the radiator from its support on both sides. Then lift out the radiator.

1956-57

Drain coolant from radiator and disconnect hoses. Remove four cap screws holding radiator to its support and lift out radiator.

1958-60

1. On air-conditioned cars, remove hood.
2. Drain coolant from radiator.
3. Disconnect transmission oil cooler lines at lower tank.
4. Disconnect hoses at radiator.
5. On air conditioned cars, remove screws securing receiver to upper grille support bar. Remove screws securing support bar to grille and radiator-fender apron support. Remove grille upper support bar. Unfasten and remove condenser from radiator.
6. Unfasten and remove radiator from its support.

1961-62

1. Disconnect battery cable.
2. Disconnect hose and transmission cooler lines from radiator.
3. Remove fan shield.
4. Remove radiator mounting bolts.
5. On air conditioned cars, unfasten condenser from radiator.
6. Remove radiator from car.

WATER PUMP, REPLACE

1955-57

Drain entire cooling system. Remove drive belt, fan blade, spacer and pulley from pulley hub. Remove generator support bracket at water pump housing.

On cars equipped with power steering, disconnect power steering pump and reservoir bracket at water pump. Remove upper and lower radiator hoses. Remove by-pass tube connection from top of water pump, and heater outlet tube connections at water pump. Unfasten water pump from engine front cover.

1958-60

1. On air-conditioned cars, remove hood and radiator.
2. Remove battery.
3. Disconnect hoses from water pump.
4. Remove belts from water pump.
5. On air-conditioned cars, unfasten power steering pump and air conditioner compressor brackets from engine.
6. Remove fan and pulleys from pump hub.
7. Remove screws attaching dipstick

Fig. 18 Oil pump. 1956-58 and 1961-62 (typical)

Fig. 19 Water pump. 1955-57

Fig. 20 Water pump. 1958-62

Fig. 21 Ignition details. 1955-57

Fig. 22 Ignition details. 1958-62

tube bracket, water pump and gaskets to engine. Remove pump and gaskets.

1961-62

1. Disconnect battery cable.
2. On air conditioned cars, remove fan shield, power booster clutch, fan and compressor drive pulley.
3. With standard cooling system, remove fan shield, fan and spacer.
4. Remove radiator supply tank.
5. Loosen clamp securing by-pass hose to water pump.
6. Remove generator splash shield.
7. Remove drive belts.
8. Remove hose from pump.
9. Remove pump mounting bolts. Then after positioning oil dipstick tube bracket and power steering pump bracket to allow removal of water pump, remove water pump.

WATER PUMP REPAIRS

1955-57

Fig. 19. Remove the snap ring from the groove in the front of the pump housing behind the pulley. (If the pump has a pressed steel pulley, remove the pulley before taking out the snap ring.) Press the shaft and bearing and pulley from the impeller. Then press the shaft and bearing and pulley from the housing. Press shaft and bearing from pulley. Press seal and sleeve from pump housing. (It is not necessary to remove the snap ring from the center of the pump housing.)

Assemble the pump in the reverse order, coating all parts lightly with cup grease. When pressing the shaft into the housing, stop applying the pressure when resistance is felt or the snap ring inside the housing will be broken. When assembled, there should be .025″ to .035″ clearance between the impeller and housing as measured with a feeler gauge.

1958-62

1. Remove impeller cover plate, Fig. 20.
2. Press shaft and bearing assembly out of impeller and pump housing.
3. Press seal out of pump housing.
4. Press shaft and bearing assembly out of hub.
5. If slinger is damaged, mark its position on shaft and then remove slinger.

Assembly

1. Remove all gasket material from mounting faces of pump and engine block.
2. If slinger was removed, install a new one, using the locating marks made before slinger was removed as a guide.
3. Coat the bearing outer diameter lightly with grease and press the shaft and bearing assembly into the pump housing.
4. Apply a thin film of waterproof sealer on a new seal and press the seal into the housing.
5. Inspect the seal rubbing face of the impeller for grooves. Replace the impeller if it is worn or damaged. Coat the rubbing face of the impeller lightly with grease.
6. Press impeller on shaft. The clearance between the impeller and impeller cover gasket surface must be 030″ to .040″ (⅛″ on 1961).
7. Position the fan hub on the shaft, then press the hub on the shaft.
8. Install a new gasket on the impeller cover and install the cover.
9. Install the pump on the engine in the reverse order of its removal.

DISTRIBUTOR, REPLACE

1. Disconnect distributor primary wire from coil terminal and remove distributor cap.
2. Unscrew vacuum line connection from vacuum advance unit.
3. Remove tachometer drive cable retaining screw and clip and pull cable and driven gear from distributor housing on models so equipped.
4. Unscrew distributor clamp bolt and remove lock washer and clip.
5. As the distributor is lifted from engine the shaft and rotor will turn counterclockwise part of a revolution. Lift distributor only far enough to disengage the gear.
6. When rotor stops turning, scribe a mark on the manifold or on engine casting to indicate the rotor position, then remove the distributor. *Do not crank the engine after the distributor is removed, otherwise the distributor will have to be initially timed to the engine.*
7. Install the distributor in the reverse order of its removal. Then start the engine, check the oil pressure and adjust the ignition timing, Figs. 21, 22.

IGNITION TIMING

Align the distributor rotor with No. 1 spark plug wire terminal in the distributor cap, when No. 1 piston is on the compression stroke and timing marks on the crankshaft pulley and pointer are aligned.

With the timing mark in line with the pointer, the distributor points should just start to open. It may be necessary to rotate the distributor body clockwise slightly and then counter-clockwise until the points just start to open. Tighten the distributor lock plate screw.

Start the engine and check the timing with a timing light.

Using Timing Light

When using a timing light, *be sure to disconnect the distributor vacuum line before checking timing,* otherwise the timing will be affected due to the fact that the vacuum opening is above the throttle plate.

Connect the timing light high tension lead to the No. 1 spark plug and the other two leads to the proper battery terminals. Clean the dirt from the timing mark and if necessary use white chalk to make the mark more visible.

Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark does not line up as the light flashes, rotate the distributor as required to bring them in alignment.

STARTER, REPLACE

1955

1. Disconnect ground cable from battery.
2. Remove cable from starter.
3. Remove two bolts attaching steering idler arm to frame lower support.
4. Remove capscrews holding end plate

to converter housing.
5. Remove starter by pulling it out and down until starter drive clears housing.

1956-57

1. Disconnect cable from starter.
2. Unfasten starter from flywheel housing.
3. Turn front wheels to extreme right position and remove starter.

1958

1. Remove ground cable from battery.
2. Remove two top drive end plate-to-flywheel capscrews.
3. Raise vehicle.
4. Remove nut from rear engine support bracket stud and raise rear of engine approximately one inch.
5. Remove cable from starter.
6. Remove lower drive end plate-to-flywheel capscrew.
7. Remove starter by working assembly forward and then down through lower suspension arms. *If equipped with power lubricator, remove two bracket retaining nuts and position power lubricator to one side to provide clearance.*

1959-60

1. Remove battery and its support.
2. Disconnect transmission control rod at accelerator shaft bracket lever.
3. Drain coolant from cylinder block.
4. Remove front engine mounting nuts.
5. Raise front end of engine as high as possible.
6. Remove right exhaust manifiiold.
7. Unfasten and remove starter.
8. If car is equipped with power lubricator, unfasten and move lubricator to one side to provide clearance.

1961-62

1. Disconnect battery ground cable.
2. Raise car and turn wheels to right.
3. Disconnect cable from starter.
4. Remove starter attaching capscrews.
5. Work starter forward and upward until clear of flywheel housing.
6. Tilt up rear of starter and with a turning motion lower assembly outward and down between No. 2 crossmember and transmission oil cooler line.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Fig. 1 Carter ABD carburetor for 1961. The 1962 carburetor is essentially the same except for the operation of the automatic choke which is now controlled by engine heated water

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in loss of power, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Do not*

use engine oil for this purpose as it will leave a residue which hampers valve operation.

1962 Carter ABD Carburetor

This carburetor, Fig. 1, is controlled by engine heated water. The heated water for the choke control is obtained from the heater hose connection located on the intake manifold of the engine. The flow from the choke control is routed from the heaters to the engine pump. Note that the water does not contact the thermostat spring. Only heat radiated from the housing jacket affects the thermostat spring.

The adjustment of the automatic choke is the same as for 1961 models. When adjusting the choke housing, do not loosen the center screw that retains the jacket to the choke coil housing. Remove the jacket retaining screw only if the jacket gasket requires replacement or the jacket requires cleaning. To remove the special retaining screw, slot out the center portion of a suitable size screwdriver blade.

Idle Speed-Up Device

1961 Carter ABD—On air conditioned cars, a mechanism is used to increase engine speed sufficiently to overcome the additional load incurred when the air conditioning unit is working, Fig. 1. This device is an electrical solenoid switch that operates an air valve in an external by-pass system of the carburetor to increase air flow. As long as the air conditioning switch is on, the solenoid is activated and holds the needle off the seat, allowing air to be admitted below the throttle plates. The solenoid is not affected by throttle position or by manifold vacuum and is controlled only by the air conditioning switch. With the incorporation of this device, it is no longer necessary to operate the air conditioning system when adjusting hot idle speed.

If there is reason to believe that the device is not functioning, check for proper vacuum by placing a finger on the air passage tube projecting through the air horn. When the unit is in operation, the vacuum pull will be felt by finger application. *Vacuum should be felt only when the air conditioning clutch is engaged.*

If engine rpm does not decrease approximately 30-40 rpm with finger applied to air inlet tube, check for current at solenoid terminals. If current is present, remove solenoid and check valve and seat. If seat is damaged, replace entire assembly. If valve is damaged, replace valve only. If both valve and seat are undamaged, and the unit is free of dirt, replace the solenoid.

Idle Air Adjustment

1961 Carter ABD—The idle air adjustment screw, Fig. 1, is used to adjust engine idle speed in a similar manner as the hot idle speed adjustment screw on conventional carburetors. Turning the air adjustment screw outward increases speed, but also leans the mixture supplied to the manifold which is compensated for by adjustment of the idle mixture adjustment screws. The initial setting of the idle speed adjustment screw is 3½ turns open.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

CARTER CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

CARTER NOTES

METERING ROD

WCFB—Metering rod adjustment must be made after pump adjustment. With throttle valves fully closed, loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—AFB float level. Adjust by bending float lever.

Fig. ②—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ③—Measure from top of bowl cover to top of plunger shaft with throttle connector rod in inner hole of pump arm. Adjust by bending throttle connector rod.

CARTER NOTES
continued

④—With engine at normal operating temperature, turn fast idle screw against low step on fast idle cam until the specified rpm is obtained.

Fig. ⑤—With throttle wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader lip on throttle lever.

Fig. ⑥—WCFB float level. Adjust by bending float lever.

Fig. ⑦—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑧—Flat on pump arm should be parallel with a straightedge placed across dust cover boss. Adjust by bending throttle connector rod.

Fig. ⑨—Measured from top surface of main body to top of free end of float in uppermost position.

Fig. ⑩—Measured from top of air horn to top of plunger shaft with pump operating rod in bottom hole. Adjust by bending pump operating rod as required.

Fig. ⑪—With throttle wide open there should be the clearance specified between upper edge of choke valve and inner wall of air horn. Adjust by bending tang on choke unloader lever.

Fig. ⑫—With throttle closed and hot idle screw against its stop, loosen dashpot locknut. Hold dashpot plunger in to the limit of its travel. There should be the clearance specified between plunger and throttle operating lever. Rotate dashpot in its bracket to obtain desired clearance.

⑬—With primary throttle valves wide open, there should be the clearance specified between top of bowl cover to top of plunger. Adjust by bending stop lug on flat lever.

⑭—Dashpot plunger shaft should bottom with the gauge size listed between shaft and operating lever with throttle valves fully closed. Adjust by turning dashpot in or out as required.

HOLLEY CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

HOLLEY NOTES

Fig. ①—Float level measured from bottom of float to floor of float bowl with bowl inverted; primary float $\frac{11}{16}''$, secondary $\frac{9}{16}''$.

Fig. ②—Float level measured from machined surface of float bowl.

③—Below machined surface of float bowl.

④—With fast idle screw against highest step on fast idle cam.

⑤—With throttle fully closed and dashpot plunger held in to the limit of its travel, there should be the clearance listed between plunger and throttle lever. Adjust by rotating dashpot in its bracket as required.

⑥—With engine running at hot idle speed, remove plugs from both sight holes. If fuel just dribbles out of sight holes, fuel level is correct. If not, adjust float level.

⑦—With primary throttle plates closed, there should be the clearance listed between the unseated bowl vent valve and vent valve seat. Adjust by bending vent arm of accelerating pump lever (not valve rod).

⑧—With throttle fully closed, hold dashpot plunger in to the limit of its travel. Then turn adjusting screw as required to obtain the clearance listed between end of screw and plunger.

⑨—With primary throttle plates held wide open, there should be the clearance listed between pump arm and hex nut on accelerating lever with pump held fully depressed. To adjust, hold hex nut and turn adjusting screw as required.

⑩—Turn fast idle screw in until it just touches low step on fast idle cam.

Automatic Transmission Section

1955-57 TURBO-DRIVE

Throttle Linkage, Adjust

1. Referring to Fig. 2, set the hand brake and set engine idle speed to 400-425 rpm with fast idle cam in low idle position and transmission in Drive range.
2. Disconnect clevis pin from transmission control-to-accelerator shaft assembly and transmission control shaft-to-transmission rod assembly at "C".
3. Disconnect carburetor-to-transmission control shaft rod assembly.
4. Insert gauge pin at point "E".
5. Adjust carburetor-to-transmission control shaft rod so that it fits freely at points "A" and "B".
6. Connect rod and remove gauge pin.
7. Pull upward on transmission control shaft-to-transmission rod to position throttle lever against its internal stop. Adjust clevis at point "C" so that clevis pin enters clevis and lever freely. Lengthen rod by turning clevis 2½ turns and reassemble.
8. With ignition off and accelerator pedal depressed to full kickdown position, adjust the length of the toggle rod so that the nylon bushing fits in the slot at point "F" with approximately ¼" clearance on Lincoln and .100" on Continental.
9. Adjust toggle rod so that it is in a vertical plane when viewed from the front of the vehicle. This is done by loosening jam nut at point "G" and turning the stud with a screw driver in the desired direction. Retighten jam nut after making the adjustment.

Manual Adjustment

1. Referring to Fig. 2, disconnect manual shift rod from selector arm at point "1".
2. Position manual lever at point "1" so that pointer at steering wheel is against stop in "DR" position.
3. Position shift lever at transmission (point "2") to second from bottom position ("DR") and adjust manual rod so that clevis pin will enter clevis and selector arm holes freely. Lengthen rod by one full turn.
4. Check position of pointer for all stations on dial.

Transmission Only, Replace

1. Drain transmission fluid.
2. Disconect drive shaft from rear axle and remove drive shaft.

Fig. 2 Turbo-Drive throttle linkage adjustments. 1955-57

3. Disconnect oil cooler lines from transmission.
4. Disconnect shift linkage at transmission.
5. Disconnect speedometer cable.
6. Remove engine rear support-to-transmission bolts.
7. Raise transmission slightly with jack to take weight off crossmember; then remove crossmember.
8. Unfasten transmission from converter and slide it back and out.

TWIN RANGE TURBO-DRIVE LINKAGE

Carburetor Rod, Adjust

1958—Refer to Fig. 3.

1. Insert ¼" gauge rod through bellcrank bracket and tab.
2. Holding carburetor lever against hot idle screw, adjust carburetor rod between points "A" and "B" so pin enters carburetor lever freely.
3. Lengthen rod pin one full turn and reassemble.
4. Remove ¼" gauge rod.
5. Adjust dashpot clearance to .045" to .065".

1959—Refer to Fig. 4.

1. Insert ¼" gauge rod through bellcrank bracket and tab.
2. Hold primary throttle shaft lever against hot idle screw and adjust carburetor rod between points "A" and "B" so rod enters primary throttle shaft lever freely.

Fig. 4 Carburetor rod adjustment. 1959

3. Remove ¼" gauge rod.
4. Check anti-stall dashpot operating lever adjustment. With primary throttle plates in wide open position, there should be a distance of $\frac{7}{16}$" between top surface of bowl and bottom of dashpot arm lever. To adjust, bend dashpot inner arm tang. With primary throttle plates closed to normal idle position, there should be a clearance of $\frac{1}{16}$" to $\frac{3}{32}$" between dashpot plunger operating lever and top surface of air horn. To adjust, bend dashpot lever in area between lever arm base and dashpot plunger.
5. Recheck hot idle rpm.

Downshift Rod, Adjust

1958-59—Refer to Figs. 5 and 6.

1. With engine shut off, depress accelerator to full kickdown position.
2. Check alignment of downshift rod. The rod must be vertical, and the bellcrank pin within $\frac{3}{32}$" from top of bellcrank slot. Release accelerator pedal when making this adjustment.
3. Looking straight down from bellcrank to Z bar, adjust screw and jam nut at point "F" so downshift rod is vertical; if not, free travel of bellcrank will be restricted. Tighten jam nuts after adjustment.
4. With accelerator pedal again depressed, the top of the bellcrank pin must be $\frac{3}{32}$" from top of bellcrank slot. At point "G", loosen lock nut and adjust downshift rod.

Throttle Rod, Adjust

1958-59—Refer to Fig. 7.

1. Install pressure gauge at rear of transmission.
2. Pull upward on throttle rod firmly but gently. Adjust clevis at point "C" so clevis pin enters freely. Lengthen clevis 3 full turns and reassemble. Total adjustment must not exceed 4 full turns.
3. Start engine and place selector lever in Dr-2 range.
4. Accelerate engine to 1000 rpm. Pressure gauge reading should be 80-95 psi.
5. To adjust pressure, adjust length of throttle rod. Lengthen clevis to increase pressure; shorten to reduce

Fig. 3 Carburetor rod adjustment. 1958

Fig. 5 Downshift rod adjustment. 1958

Fig. 6 Downshift rod adjustment, 1959-60

pressure. *Do not operate engine for long period at 1000 rpm as transmission will overheat.*

Manual Linkage, Adjust

1958-59—Refer to Fig. 8.

1. Disconnect manual rod clevis at point "1".
2. Position selector lever at point "2" so pointer is against stop in Dr-1 range. (Hold this position throughout the manual adjustment.)
3. Position detent lever in second position (Dr-1) from bottom.
4. Adjust manual rod clevis so pin enters clevis and detent lever freely. Lengthen clevis one full turn and reassemble.
5. Check position of quadrant pointer in each range. If pointer is off location, adjust the position of the letters. Do not adjust linkage to correct pointer alignment.

1960 Adjustments

Carburetor Rod, Fig. 9:

1. Disconnect throttle rod at point C.
2. Disconnect carburetor rod at point A.
3. Insert ¼" gauge pin through alignment holes in bellcrank bracket and tab, point D.
4. While holding carburetor lever against hot idle adjusting screw, adjust length of carburetor rod between points A and B for free fit into carburetor lever. Lengthen rod one turn.
5. Remove gauge pin and connect carburetor rod.

Throttle Rod, Fig. 10:

1. Raise hood and connect pressure gauge as shown.
2. Pull upward on throttle rod firmly but gently. Adjust clevis at point C so clevis pin enters freely. Lengthen clevis 3½ turns and reassemble throttle rod.
3. Start engine and with foot brake set firmly, place selector lever in D2 position.
4. Accelerate engine to a fast idle (1000 rpm). Pressure gauge reading must be 80-85 psi. To correct the pressure, adjust length of throttle rod. Lengthen clevis to increase or shorten to reduce pressure. *To avoid overheating transmission, selector must be returned to neutral position and throttle closed after each check.*

Downshift Rod, Fig. 6:

1. With ignition off, depress accelerator to full kickdown position. Check position of bellcrank rod and pin. Check alignment of downshift rod. Downshift rod must be vertical and the bellcrank pin within 3/32" from top of bellcrank slot. Release accelerator pedal when making adjustment.
2. Looking straight down from bellcrank to the "Z" bar, adjust screw and jam nut at point F so downshift rod is vertical with relation to sides of car. If downshift rod is

Fig. 7 Throttle rod adjustment. 1958-59

Fig. 9 Carburetor rod adjustment, 1960

Fig. 10 Throttle rod adjustment, 1960

not vertical, free travel of bellcrank will be restricted. After adjustment, tighten jam nuts.

3. With accelerator again depressed, top of bellcrank pin must be within $\frac{3}{32}$" from top of bellcrank slot. To adjust, snap downshift rod off stud at point F and lengthen or shorten rod as required to obtain correct linkage travel.

Manual Linkage: This adjustment is made as outlined for 1958-59 models.

1961 Linkage, Adjust

Downshift Rod, Fig. 11

1. Loosen locknut on downshift rod. Disconnect rod from ball stud on bellcrank and slide off spring clip. Make sure movable outer bracket on bellcrank is up against stop pin on inner mounting bracket on bellcrank.
2. Pull upward and hold downshift rod against transmission internal stop. Adjust length of rod until hole in rod is aligned with ball stud on bellcrank.
3. Loosen downshift rod one turn and position it on ball stud. Slide spring clip over end of rod to lock rod to stud. Tighten lock nut. *Be sure outer bracket remains against stop pin; if not lengthen downshift rod one additional turn.*

Accelerator Pedal Height, Fig. 11

1. With engine off, measure distance from top of pedal to carpet, which should be approximately 4¾".
2. Depress accelerator pedal and check for detent feel and kickdown action of bellcrank. Be sure carburetor throttle plates are fully closed. Then adjust pedal height at accelerator connecting link to achieve proper operation of downshift rod.

Manual Linkage, Fig. 12

1. With engine shut off, place selector lever against stop in "D1" position.
2. Raise car and disconnect adjustable link from manual shift lever at transmission.
3. Loosen locknut on adjustable link. Pull down on link to hold selector lever against stop. Lengthen or shorten link by rotating its lower end until hole in link aligns with stud on transmission shift lever. Lengthen link one-half additional turn and connect it to transmission shift lever.
4. Check selector lever through all ranges to assure correct adjustment.

Fig. 8 Manual linkage. 1958-60

TRANSMISSION, REPLACE

1961-62

It is necessary to remove the complete transmission and converter housing as a unit as there is one additional attaching bolt located behind the converter where it is not accessible until after the converter has been removed.

1. Drain transmission oil pan. Remove converter access cover from front of converter housing. Remove transmission linkage splash shield.
2. *Mark rear universal joint flange and pinion flange before removing drive shaft so it can be reinstalled in same position, thus maintaining original balance.*
3. Disconnect parking brake cables and equalizer.
4. Disconnect linkage from transmis-

Fig. 11 Accelerator linkage and downshift rod adjustments. 1961-62

sion levers and vacuum hose at vacuum diaphragm. Disconnect speedometer cable.
5. Remove three upper converter housing-to-engine bolts. Remove nuts attaching converter to flywheel.
6. Turn front wheels to right and remove starter motor. Raise transmission slightly with a jack. Remove crossmember.
7. Detach vacuum line at converter housing. Remove manual linkage equalizer mounted between transmission and underbody.
8. Remove remaining transmission-to-engine bolts and remove transmission and converter assembly from car.
9. Reverse removal procedure to install. Adjust linkage as outlined previously.

1960

It is necessary to remove the complete transmission and converter housing as a unit as there are two additional attaching bolts located behind the converter where they are not accessible until after the converter has been removed.

1. Disconnect accelerator linkage (downshift rod) from bellcrank.
2. Remove two upper and one bolt from right side of converter housing-to-engine. Remove one inner upper bolt attaching starter motor to converter housing.
3. Disconnect engine stabilizer bracket from converter housing. Remove converter housing lower plate.
4. Drain converter and transmission.

Fig. 12 Manual linkage adjustments. 1961-62

5. Remove exhaust crossover pipe.
6. Disconnect oil cooler lines.
7. *Before removing drive shaft, mark rear universal joint and axle shaft flange so it can be reinstalled in same position, thus maintaining original balance.*
8. Disconnect parking brake cables from equalizer bar and remove bar.
9. Detach starter and slide it forward over frame crossmember and secure in place.
10. Remove control linkage splash shield. Disconnect linkage from transmission; also speedometer cable.
11. Remove nut from engine rear mount lower stud.
12. Support transmission with jack and remove rear mount from crossmember and remove crossmember by sliding it over left exhaust pipe to rear of left mounting bracket. Lower transmission slightly and remove remaining converter housing-to-engine bolts.
13. Remove transmission from car.
14. Reverse removal procedure to install and adjust linkage as outlined previously.

1958-59

The transmission can be removed from the car, leaving the converter housing attached to engine. The procedure is as follows:

1. Disconnect battery.
2. Drain transmission fluid.
3. Disconnect linkage from transmission.
4. Disconnect speedometer cable.
5. Remove drive shaft.
6. Disconnect parking brake equalizer from its lever.
7. Disconnect parking brake cable from equalizer lever and remove lever.
8. Position jack under transmission. Relieve weight on rear engine mount and remove mount and support member.
9. Lower jack until engine just rests on frame crossmember.
10. Unfasten transmission from converter and slide it back and out.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE, REPLACE

Inasmuch as the differential carrier is part of the rear axle housing, it is advisable to remove the entire rear axle assembly if the differential is to be overhauled. The procedure is as follows:

1. Lift the rear of the car with a chain hoist attached to the bumper.
2. Set chassis support stands under the frame side rails ahead of the front spring hangers.
3. Drain the differential housing.
4. Remove axle shafts and propeller shaft.
5. Remove hydraulic brake line clips from axle housing and free brake line from differential housing. Wire hydraulic line to frame.
6. Raise axle housing with a jack until shock absorbers start to compress. Remove nut holding shock absorber to spring seat.
7. Remove U-bolts attaching axle housing to rear springs.
8. Lower axle assembly to floor.

REAR AXLE REPAIRS

In this type axle, Fig. 1, the drive pinion is held in position by shoulders in the differential carrier, upon which the pinion bearing cups seat. The pinion position is maintained by shims located between the rear bearing and the rear shoulder in the differential carrier. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The shimmed type of differential bearing adjustment is employed. The procedure for making this adjustment, as well as the assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

The axle tubes are pressed into the differential carrier to form a one-piece housing. To overhaul the unit, therefore, the rear axle assembly must be removed from the chassis.

Pinion & Bearings, Replace

After removing the axle shafts and

Drive shaft and universal joints. Typical of all 1955-60

Fig. 1 Rear axle. 1955-62

differential unit, unscrew the pinion flange retaining nut and pull off the flange. The pinion may then be removed from the carrier by driving it out of the front bearing with a brass drift and hammer. After the pinion is free of the front bearing, pull it out through the rear of the carrier.

Mount the pinion in a press and press the pinion shaft out of the bearing. When replacing the bearing select a suitable sleeve or length of pipe of the same diameter as the cone so the rollers or cage will not be damaged when being forced on the shaft.

Drive the front bearing cup and oil seal out of the forward end of the carrier. If the rear bearing cup is to be replaced or if the pinion setting is to be changed, remove the rear bearing cup.

To change the pinion setting, the shims behind the rear bearing cup should be measured with a micrometer. The necessary shims may then be removed or added to obtain the proper pinion setting as indicated when a pinion setting gauge is used (see *Rear Axle* Chapter). After the required shims have been added or subtracted, replace the rear bearing cup.

When making a pinion adjustment, the same thickness of pinion bearing adjusting shims should be added or removed at the rear bearing cup to retain the proper pinion bearing adjustment.

To install the pinion, support it under the head with a wood block while the pinion flange is reinstalled. The pinion oil seal should not be replaced until after the pinion setting has been checked.

Drive shaft and universal joints. 1961-62

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearing are tight, but still permit rotating the pinion by hand.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion may be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle* Chapter. If a correction is necessary, disassemble the pinion and, if it is to be moved toward the center of the axle, add shims between the rear bearing and rear shoulder in the carrier. If the pinion has to be moved away from the center of the axle, remove shims from this point.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle* Chapter. After satisfactory tooth contact has been established, remove the pinion flange to install the seal.

Axle Shafts

Axle shafts are mounted on sealed ball bearings pressed to a shoulder on the axle shaft, and held in place by a pressed-on bearing retainer ring. The shaft bearings are pre-lubricated and require no additional lubrication. The shafts are held in place in the axle housing by a retainer plate. The wheel hub and brake drum flange are forged integral with the axle shaft. The flange provides the brake drum and wheel mounting and eliminates the need for a keyed hub.

Axle Shaft, Remove

To remove an axle shaft, take off the wheel and unfasten the brake drum from the axle shaft flange. Through the hole provided in the flange, remove the nuts which secure the brake support plate to the axle housing. Then with a suitable puller, pull the shaft out of the housing, using care not to dislodge the brake support plate or damage the oil seal in the housing. Install one nut to hold the brake plate in position.

Bearing, Replace

Axle shaft bearings should be removed only when necessary to install a new bearing. A bearing once removed must be discarded.

If necessary to disassemble, loosen the axle shaft bearing retainer ring and remove the retainer. The bearing may be removed with a bearing puller, after which remove the retainer plate.

To assemble, place the retainer plate on the shaft. Press the bearing up against the shoulder on the shaft. Install the bearing retainer ring and press it firmly against the bearing. Before installing the shaft examine the oil seal and replace it if necessary.

Oil Seal, Replace

Before installing a new oil seal it should be thoroughly soaked in oil for at least ½ hour to make it soft and pliable. When installing the seal, use a suitable seal driver, driving the seal into the axle housing with the axis of the shaft and tight against the shoulder. After installing the seal, check the outer diameter for tightness in the housing to avoid possible leaks.

Axle Shaft, Install

To install the shaft, remove the temporary nut holding the brake plate, and lubricate the bearing bore in the housing. Clean the brake plate surface and install new gaskets between the retainer plate and brake plate. Slide the shaft into the housing, using care not to damage the oil seal. Push the shaft in until its bearing is tight against the shoulder in the housing. Complete the job by tightening the axle shaft nuts to 30-35 pounds feet torque, and install the brake drum and wheel.

POWER BRAKE UNIT, REPLACE

1955

Repairs on the power brake unit are given in a separate chapter. To remove and install the unit from the vehicle, proceed as follows:

1. Working inside the car under the instrument panel, disengage valve push rod from brake pedal.
2. Working in engine compartment, remove master cylinder outlet fitting bolt from master cylinder. *It is not necessary to remove the stop light switch, wires or hose assembly from the outlet fitting. Do not disturb the outlet fitting.*
3. Remove manifold vacuum hose from check valve on power unit.
4. Remove vacuum reserve tank hose from fitting on check valve.
5. Unfasten power brake assembly (4 screws) from bracket on dash panel.
6. To install, reverse foregoing procedure. Then bleed brakes in the usual manner. After bleeding, fill hydraulic brake reservoir to within ¼" of the top of filler cap opening and replace cap.

1956-57

1. Working in engine compartment, remove master cylinder outlet fitting bolt from master cylinder. It is not necessary to remove stop light switch.
2. Remove manifold vacuum hose from check valve on power unit.
3. Remove vacuum reserve tank hose from fitting on check valve.
4. Unfasten and remove power unit from dash panel.
5. To install, reverse foregoing procedure. Then bleed brakes in the usual manner. After bleeding, fill reservoir to within ¼" of the top of the filler cap opening and replace cap.

1958-61

1. From inside car, disengage push rod from lever.
2. From engine compartment, remove master cylinder outlet fitting. It is not necessary to remove stop light switch.
3. Remove manifold vacuum hose from power unit.
4. Remove shoulder bolt retaining booster push rod from pedal linkage.
5. Unfasten and remove power unit from dash panel.
6. To install, reverse foregoing procedure. Bleed brake system in usual manner. Then fill master cylinder to within ¼" of filler cap opening and replace cap.

Front End and Steering Section

WHEEL ALIGNMENT

1961-62 Caster

1. Raise hood and unsnap clips retaining top of rubber bushing shield to fender apron.
2. Loosen bolts that secure upper control arm shaft to frame and, with a pry bar, move shaft in or out as required. A movement of approximately $\frac{3}{32}$" at either front or rear bolt location will change caster ½°. Inboard movement of the front bolt, or outboard movement of rear bolt, will change caster in negative direction. Outboard movement of front bolt or inboard movement of rear bolt will change caster in positive direction.
3. When adjustment is correct, torque shaft retaining bolts to 100-125 ft. lbs.

1961-62 Camber

1. Raise hood and unsnap clips retaining top of bushing rubber shield to fender apron.
2. Loosen bolts that secure upper control arm shaft to frame and, with a pry bar, move shaft in or out as required. A movement of approximately $\frac{3}{64}$" of the entire shaft will change camber ¼°. Inboard movement will change camber in negative direction. Outboard movement will change camber in positive direction.
3. When adjustment is correct, torque shaft retaining bolts to 100-125 ft. lbs.

1955-60 Caster & Camber

To adjust caster, Fig. 2, loosen the two bolts that secure the upper suspension arm shaft to the frame and insert shims between the shaft and frame.

A $\frac{1}{16}$" shim at the front bolt will produce a negative caster of ½ degree. A $\frac{1}{16}$" shim at the rear bolt will produce a positive caster of ½ degree. Shims are available in thicknesses of $\frac{1}{64}$", $\frac{1}{32}$", $\frac{1}{16}$" and ⅛". When the correct adjustment is obtained, torque the bolts to 75-80 lbs. ft. Caster must be held within ½ degree difference on both sides.

Camber is also adjusted at the upper suspension shaft. To adjust, insert or remove the shims from between the shaft and the frame at both the front and rear bolts. Each $\frac{1}{16}$" shim removed will add ¼ degree of positive camber. The camber must be the same on both sides within ¼ degree.

1955-62 Toe-In

Position the front wheels in their straight-ahead position. Then turn both tie rod adjusting sleeves an equal amount until the desired toe-in setting is obtained.

WHEEL BEARINGS, ADJUST

1955-60

1. Tighten spindle nut with a 12" wrench, while rotating wheel back and forth, until there is a noticeable drag or bind. This assures that bearing cones are properly seated.
2. Then back off spindle nut to line up to the nearest cotter pin hole that will allow the hub to rotate freely with no perceptible end play.

1961-62

With wheel rotating, torque spindle nut to 15-20 ft. lbs. Locate nut-lock on spindle nut so that cotter pin castellations are aligned with cotter pin hole in spindle. Back off spindle nut and nut-lock together until next castellation on nut-lock aligns with cotter pin hole in spindle, and install cotter pin.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure front wheel bearings are properly adjusted and that control arms are tight. Then check ball joints for wear as follows:

A method of checking friction load on upper joints by means of a torque wrench is provided. After separating upper joint from steering knuckle, the joint stud nut is installed and tightened on the stud. The stud is then turned in its socket with an inch-pound torque wrench. Torque should range from 20 to 35 inch pounds. If reading is below the minimum, replace the joint.

To check the lower joint, jack up under the frame rather than under the lower control arm to maintain coil spring load on lower joint. Then grasp the tire at the top and bottom and move it in and out. If movement at edge of tire exceeds ⅛", ball joint is worn and should be replaced.

Fig. 1 Front suspension. 1961-62

FRONT END REPAIRS

1955-62

This suspension, Figs. 1 and 2, is the ball joint type. It differs from other types of suspension in that the wheel spindle is attached directly to the suspension arms by means of ball joints located at the outer ends of both arms. The conventional steering knuckle, knuckle support and kingpin is eliminated.

Shock Absorber

To remove a shock absorber, unfasten it from the frame at its upper end. Remove the two cap screws that retain the shock absorber mounting plate to the lower conrol arm and lower the shock absorber unit.

To install, reverse the removal procedure and tighten the two lower cap screws to 18-24 lbs. ft. torque.

Lower Control Arm & Spring

Raise the front of the car and place a support stand under each frame side rail to the rear of the lower control arm. Remove the hub cap and pry off the grease cap. Remove the nut from the wheel spindle and pull off the wheel assembly with hub and brake drum.

Remove the shock absorber as outlined above and detach the stabilizer bar from the lower control arm.

Loosen the slotted nut which attaches the lower ball joint stud to the lower spindle boss one or two turns. Then with a brass bar and hammer, strike the lower spindle boss to pop the stud loose against its nut. Place a jack under the outer end of the lower arm and raise the jack until the upper arm rebound bumper is clear of the frame. The nut can then be removed and the spindle and brake assembly lifted off the ball joint stud and moved out of the way.

Lower the jack until the coil spring is free and can be removed. Note the rubber insulators at the upper and lower ends of the spring.

Unfasten the lower control arm from the frame and remove the arm. Inspect the bushings on the inner end of each arm leg and replace if defective.

INSTALL—To install the lower control arm, secure the rearward leg to the

Fig. 2 Front suspension. 1955-60

frame crossmember tube, running the nut up finger tight. With the arm forced firmly against the tube, install enough shims to fill the space between the forward arm leg bushing and front crossmember. Then install the bolt and washers and run the nut up finger tight. With the arm in curb load position (approximately horizontal) with the outer end slightly lower than the inner, tighten the nuts to 80-100 lbs. ft. torque.

Place the coil spring with the rubber insulators in position on the lower control arm. Then with a jack under the lower arm, compress the coil spring. Care must be taken to see that the upper and lower ends of the spring are properly seated and the rubber insulators are in place. Guide the spindle boss over the ball joint stud. Install the nut and torque it to 100 lbs. ft. Continue to tighten until the cotter pin holes are lined up and install the cotter pin.

Remove the jack from under the arm and install the shock absorber. Secure the stabilizer bar to lower suspension arm.

Ball Joints

Remove the cover and seal from the ball joint. Inspect the joint and replace if found defective. If the joint is still serviceable, *do not* wash it in solvent as it will be extremely difficult to lubricate it again. Do not hammer the ball joint bodies as binding will result. Inspect the metal seal parts for damage and replace if necessary. Replace the sponge rubber seal, making sure it is stuffed into the metal seal cup before pushing it down over the ball joint stud.

Upper Arm

Remove the shock absorber. Place a jack under the lower control arm spring seat and raise it until some of the tension has been removed from the upper bumper. Remove the wheel and tire assembly.

Wire the spindle to the frame to avoid possible damage to the brake hose from undue tension. Loosen the ball joint stud by backing the nut off one or two turns and striking the spindle boss. Remove the stud nut completely and then remove the two bolts that secure the inner shaft to the frame. Note the number of shims between the shaft and frame at each of the bolt locations. Then take off the upper control arm.

To install, position the arm on the frame crossmember. On models before 1961, use the same number of shims that were originally used between the shaft and frame bracket. Secure the shaft to the bracket with the two bolts and torque the bolts to 75-90 lbs. ft. (100-125 on 1961). Place the ball joint stud in the spindle boss, install the nut and tighten it to 80 lbs. ft. minimum. Continue to tighten until the cotter pin holes are lined up and install a cotter pin.

Install the wheel and hub assembly and remove the jack from under the lower control arm. Finally, check the wheel alignment as previously outlined.

HORN SOUNDER & STEERING WHEEL

1960-62

1. Remove cap from steering wheel hub by pressing cap and turning counterclockwise.
2. Remove nut from steering shaft.
3. Use puller to remove wheel and horn ring assembly.
4. When installing wheel and horn ring, align mark on wheel hub with mark on shaft. Install nut and stake in place.

1958-59

1. Remove cap and emblem from wheel by inserting a flat tool below steering wheel hub and push up.
2. Remove steering shaft nut and use puller to remove wheel.
3. Install wheel with mark on wheel hub aligned with mark on steering shaft.

1955-57

1. Remove cap and emblem by grasping with the hand and pulling outward from wheel hub.
2. Remove steering shaft nut and remove wheel with a puller.
3. Install wheel with mark on wheel hub aligned with mark on steering shaft.

STEERING GEAR, REPLACE

1955

1. Remove clamp that secures reservoir hose to fitting on brake booster cylinder (if equipped).
2. Remove clamp that secures reservoir hose to dash panel. Move hose away from steering column opening in dash panel.
3. Remove front seat cushion.
4. Remove steering wheel.
5. Disconnect steering column electrical connections.
6. Remove accelerator pedal from accelerator push rod. Remove bolt and clevis pin securing brake pedal to brake pedal support and push rod, and remove brake pedal.
7. Remove sheet metal screw, located under accelerator pedal, securing floor carpeting to floor pan and pull carpeting away from dash panel opening.
8. Disconnect speedometer drive cable from instrument panel and pull it through lower floor pan opening cover. Remove insulator and floor pan opening cover plates.
9. Remove two cap screws that secure steering column bracket to instrument panel and pedal support bracket.
10. Release shift rod from steering column shift arm.
11. Loosen clamp on lower steering column at steering gear housing. Raise column sufficiently to disconnect wires at neutral switch on Automatic Transmission equipped models only. Remove steering column tube from

steering shaft through inside of vehicle.
12. Raise front of car and remove pitman arm.
13. Loosen three bolts that secure steering gear to frame. *Remove shims, if any, located between mounting bolts and frame side rail. Mark bolt holes and number of shims required to facilitate assembly. Mark shims for identification with bolt holes.*
14. With one man in the passenger compartment and another under the vehicle, remove the three steering gear mounting bolts that were previously loosened and remove the steering gear through the passenger compartment.

POWER STEERING UNIT, REPLACE, 1955

1. Unfasten reservoir hose from power brake fitting on vacuum cylinder.
2. Unfasten reservoir hose from fire wall. Pull hose to engine side of floor pan opening cover to provide working clearance.
3. Remove front seat cushion.
4. Remove steering wheel.
5. Disconnect steering column electrical connections.
6. Detach accelerator pedal from its push rod.
7. Remove brake pedal from its support bracket.
8. Remove sheet metal screw (under accelerator pedal) and pull carpet away from floor pan opening.
9. Unfasten insulator from floor pan cover plates and pull insulator up on steering column.
10. Unfasten lower floor pan cover from floor pan.
11. Disconnect speedometer drive cable from instrument panel and pull it through lower floor pan opening.
12. Unfasten upper floor pan cover from floor pan.
13. Remove steering column support bracket from instrument panel.
14. Detach release shift rod from steering column shift arm.
15. Loosen clamp on lower steering column at the gear housing and raise column enough to permit the wires to be disconnected from the neutral switch.
16. Pull column from steering shaft through inside of vehicle.
17. Disconnect hoses from steering gear valve housing. *Secure hoses in upward position to prevent leakage of oil.*
18. Raise front of car and use a suitable puller to remove pitman arm.
19. Loosen three bolts securing steering gear to frame side rail.
20. Remove shims, if any, located between mounting bolts and frame. *Mark bolt holes and number of shims at each bolt hole to assure correct assembly.*
21. With one man in driver's compartment and another under the car, remove the three previously loosened gear-to-frame bolts and lift the steering gear through the passenger compartment.
22. Install the unit by reversing the foregoing procedure.

1956-57

1. Remove battery ground cable.
2. Remove radio speaker.
3. Remove steering wheel.
4. Disconnect speedometer cable.
5. Disconnect accelerator rod.
6. Remove brake pedal pad.
7. Remove steering column supports.
8. Remove access covers from floor.
9. Remove shift rod from pin on shift arm.
10. Disconnect turn signal wires at junction block. Also neutral switch and back-up light wires attached to terminal block on steering column.
11. Remove steering column from steering shaft.
12. Working through floor pan opening, remove rear manifold cap screw.
13. Raise car and remove pitman arm from steering sector shaft.
14. Unfasten muffler inlet to manifold.
15. Remove two forward screws that secure steering gear to frame side rail. Leave remaining screw in place until remaining operations are accomplished. Mark position of any shims found under screws to insure proper assembly.
16. Lower car to complete operations in engine compartment.
17. Remove manifold, and spark plugs from cylinder Nos. 6, 7 and 8 and on Continental, remove air cleaner and air duct as an assembly.
18. Remove as much fluid as possible from reservoir with suction gun.
19. Place drain pan under car to catch oil drained from system.
20. Disconnect pressure and return lines at power steering gear. Drain steering gear by turning from stop to stop several times.
21. Remove remaining steering gear-to-frame attaching bolt.
22. Place steering shaft with coupling slot in a vertical position to facilitate removal. Remove gear by tilting gear housing down and rearward until sector shaft can be removed first.
23. Reverse the removal procedure to install the steering gear. Fill the pump reservoir to the proper level. Loosen bleed screw in side cover and start engine. Turn steering wheel several times through its entire range to bleed all air from system. Tighten bleed screw and recheck fluid level.

Fig. 3 Exploded view of manual steering gear. Typical of all 1955

1958-60

1. Remove pressure and return lines from steering gear. Elevate the lines to minimize fluid leakage.
2. Remove power brake unit.
3. Unfasten steering shaft coupling from steering gear.
4. Remove pitman arm with a suitable puller.
5. Remove 3 bolts securing steering gear to underbody side rail.
6. Remove steering gear from car.
7. Reverse the foregoing procedure to install the gear. Then bleed the brake system and power steering system.

1961

1. Remove splash shield at pitman arm and pull off pitman arm.
2. Disconnect hoses from gear and tie hose ends higher than reservoir to prevent fluid loss.
3. Loosen Allen screw that attaches flexible coupling to steering shaft. Use an Allen socket and a universal joint to loosen screw.
4. Disconnect resonator inlet pipe at exhaust manifold and resonator and remove pipe.
5. Remove transmission linkage rods from equalizer shaft and force shaft outward. This compresses spring within shaft which frees shaft from inner ball joint.
6. Unfasten gear housing from body member and remove gear assembly.
7. Installation is the reverse of removal. Fill reservoir. Before checking fluid level, turn steering wheel from one extreme to the other and operate windshield wipers. This bleeds system of air and assures that it is filled with fluid.

MANUAL STEERING GEAR, ADJUST

1955, Fig. 3

Before proceeding with the adjustments, loosen the gear housing from the frame side rail to relieve any possible vertical strain. Loosen the steering column clamp to relieve any possible horizontal strain. Then tighten the mounting and clamp bolts which will relieve any misalignment in the steering gear mounting.

Steering gear adjustments must be made in the order given below to insure satisfactory results.

Worm Bearing Preload

The worm bearing preload is controlled by the shim pack installed between the steering gear housing and the housing upper cap. The shim pack contains shims of various thicknesses; the thinner shims are installed on the top of the pack, and the adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Turn the steering wheel two complete turns from the straight-ahead position. Hook a spring scale to the steering wheel rim. Rotate the wheel at least one turn with the aid of the scale. The pull required to keep the wheel moving should be between ⅛ and ⅝ lbs., which is the worm bearing preload. If the reading is high, a shim or shims should be added. If reading is too low, remove a shim or shims.

If an adjustment is required, unfasten the upper cap from the housing and work the cap and column jacket upward to allow clearance for removing or adding shims. For additional working clearance it may be necessary to remove the steering wheel.

To add a shim, split the shim at one point and install the shim with the split in the upward position. Make sure the split ends do not overlap as this could lead to a false adjustment.

To remove a shim separate the first shim from the pack with a knife blade. Pass the blade all around the shim, being careful not to damage the shims.

The steering column and upper housing cap must be assembled on the gear housing each time the preload is checked.

Worm & Roller Mesh

This adjustment is controlled by the adjustment screw mounted on the sector shaft cover. Adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Attach a spring scale to the steering wheel rim. Pull the wheel through the straight-ahead position and note reading on scale. The scale reading should be at least ½ lb. above that of the worm bearing preload previously determined, but the total reading must not exceed 1⅝ lbs. If the scale reading does not exceed the worm bearing preload by at least ½ lb., the worm and roller mesh should be adjusted.

Place the steering wheel in the straight-ahead position. Remove the adjusting screw cover and lock washer. Rotate the adjusting screw clockwise while moving the steering gear arm back and forth until all backlash is removed.

Install the lock washer and cover and check the preload with the spring scale as previously described. The reading should be between 1 and 1⅝ lbs. If the reading is too high, turn the adjusting screw slightly counterclockwise. If too low, turn the screw slightly clockwise.

STEERING GEAR REPAIRS

1955

1. Drain lubricant from housing.
2. Remove sector shaft and cover.
3. Remove cover from sector shaft.
4. Unfasten and slide housing cap off steering shaft.
5. Pull shaft out of housing.
6. Slide housing upper cap gaskets (shim pack), bearing cup, and upper worm bearing out of housing.
7. Use suitable puller to remove lower worm bearing cup.
8. Press sector shaft needle bearings and oil seal through steering arm end of housing.

Inspect & Assemble, Fig. 3

After cleaning all parts, inspect worm and rollers for scores, cracks or for signs of chipping. Inspect steering shaft bearing cups and bearings for wear, cracks or damage. Check sector shaft for wear at needle bearing locations. Replace all parts that are damaged enough to impair steering gear operation, and assemble the steering gear in the reverse order of disassembly.

Instruments, Radio and Windshield Wiper

INSTRUMENTS

1955

To remove the speedometer or any one of the dash instruments, first remove the radio. The instruments or speedometer can then be removed individually by removing the screws from the back edge of each instrument.

1956-57

The speedometer forms part of the instrument cluster assembly, which is removed as follows:

1. Disconnect battery ground cable.
2. Remove radio speaker and radio.
3. Disconnect speedometer cable.
4. Remove odometer cable and knob from lower edge of lower control panel.
5. Unfasten and remove instrument cluster.
6. Remove speedometer from panel.

1958-59

1. Disconnect battery ground cable.
2. Remove instrument cluster top cover plate.
3. Disconnect wiring and socket and bulbs around speedometer area to provide clearance. Note position and color codes of wires to facilitate reassembly.
4. Disconnect speedometer cable.
5. Remove instrument panel left lower cover plate.
6. Remove trip odometer reset cable from lower lip of instrument panel.
7. Unfasten and remove speedometer (6 screws).

1960

The top row of instruments and gauges are grouped in four pod-like assemblies. To service the pod assemblies (one of which contains the speedometer), remove the instrument cluster hood, remove two

pod-to-cluster retaining screws and disconnect the wiring and bulbs.

To remove the instrument cluster hood, remove three screws, one at each end of the hood and one in the center. On air conditioned models, it is necessary to remove the left hand instrument panel air conditioner grille upper moulding (3 screws) to gain access to the left hand cluster hood retaining screw.

1961

The instrument panel is composed of two clusters, upper and lower. The upper cluster consists of three housings that can be serviced from the front of the instrument panel. The lower housing is removable in two sections.

All lamps in the upper cluster can be replaced from the front of the cluster. To replace the lamps in the temperature and fuel gauge housing, remove the bezel and gauges and replace the lamps. To replace the lamps in the speedometer housing, it is necessary to remove the speedometer to replace the high beam indicator and/or the two upper background lamps.

To replace the bulbs in the lower cluster, remove the lower speaker and grille assembly. Remove hood release handle and bracket from instrument panel. Remove lower left instrument panel cover and replace lamp bulbs as required.

1962

The speedometer housing and printed circuit board is mounted from the passenger side of the instrument panel and is retained to the mounting and trim plate by four screws.

1. Remove speedometer housing bezel by loosening two lower retaining screws.
2. Remove four screws retaining speedometer housing and printed circuit board to mounting and trim plate.
3. Pull speedometer housing away from panel. Disconnect speedometer cable and printed circuit board connector.
4. Remove speedometer housing and printed circuit board.

RADIO REMOVAL

1961-62

1. Disconnect battery ground cable.
2. Pull off radio control knobs and remove outer bezel.
3. Remove large bezel (4 screws).
4. Unfasten and slide trim panel (2 screws) away from windshield to remove it.
5. Disconnect feed and panel lamp bullet connector and antenna lead-in cable.
6. Unfasten radio (3 screws) and pull radio and support out of instrument panel.

1958-60

Tuning Head—The negative battery cable should be disconnected to eliminate the possibility of shorting while removing the tuning head as the ignition switch is close to the path of removing.

1. Remove instrument panel top cover.
2. Remove instrument panel lower cover panel.
3. Remove power lubricator lines and control assembly from instrument panel.
4. Remove cigar lighter.
5. Remove fuse holders as required.
6. Remove manual selector control knob and speaker control disc.
7. Remove volume control knob and tone control disc.
8. Remove mounting nuts retaining shafts to instrument cluster.
9. Disconnect five wires at left of tuning head, and two fuse holders from fuse panel.
10. Disconnect antenna lead-in cable.
11. Remove right instrument panel lower cover panel.
12. Disconnect tuning head lower coaxial cable from audio chassis plug.
13. Disconnect speaker jacks from top of tuning head.
14. Remove tuning head rear brace.
15. Lower tuning head out of instrument panel.

Audio Chassis—

1. Remove right instrument panel lower cover panel.
2. Disconect coaxial cable at audio chassis.
3. Unfasten chassis (3 screws) and lower it down and out from rear of panel.

4″ Speaker—In order to remove this speaker, remove glove compartment and glove compartment cover.

6″ x 9″ Right Instrument Panel Speaker—Remove instrument panel right lower cover panel. Unfasten speaker (2 wing nuts) from panel. Lower speaker a few inches, then disconnect lead cable and 4″ speaker cable and complete removal.

WINDSHIELD WIPER

1955-57

Wiper Motor—Removal of the wiper motor is fairly obvious. However, when installing be sure the rubber gasket is on the motor shaft end, and is inserted evenly into the auxiliary drive.

Pivot Shaft Housing—When removing the pivot shaft housing it will be necessary to remove the glove compartment box (1956-57) and defroster outlet on right side. Pull the cable tensioner toward the center of the car and lock in this position with a drift pin through the hole provided.

When installing, be sure to rig the cables properly on the pulleys before connecting to the auxiliary drive. Then take the drift pin out of the cable tensioner and allow the pulleys to take up the slack in the cables.

1958-60

The cable tension is secured to the rear of the auxiliary drive. Cable tension can be automatically increased by loosening the wing nut on the tensioner and retightening the wing nut.

To gain access to the auxiliary drive and wiper pivot, it will be necessary to remove the center, right and left lower instrument panel covers, and also the glove box and its cover.

1961-62

1. Remove washer coordinator hose from bottom of wiper motor.
2. Remove oil return, feed and control lines from wiper motor.
3. Disconnect cable at motor.
4. Remove motor (2 screws) from auxiliary drive mounting plate and remove motor.

①—Engine numbering (front to rear): Right bank 1–2–3–4, left bank 5–6–7–8.
②—On air conditioned cars, set idle speed with air conditioner operating for a minimum of 20 minutes.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

Engine Section

ENGINE, REPLACE

1955-60

1. To remove engine separately from transmission, remove hood, air cleaner, battery, radiator, fan, heater blower and duct, power brake and power steering pump.
2. Remove oil filter and starter. When removing starter on 1955, turn wheels to extreme left turn position and pull starter down between tie rods and tubular engine support crossmember.
3. On 1956-60 remove radiator splash shield.
4. Remove fuel lines, vacuum lines, accelerator linkage as necessary, hoses and wires attached to engine hoses and wires attached to engine.
5. On standard and overdrive transmissions, disconnect clutch release rod from release lever. Remove equalizer bracket from flywheel housing. Allow equalizer bar and release rod to hang down from frame.
6. On 1955, disconnect accelerator linkage from firewall, allowing linkage to stay on engine.
7. Remove converter access covers from bell housing.
8. Detach exhaust pipes from manifolds.
9. On 1955 unfasten flex plate from converter.
10. Remove capscrews securing engine to flywheel housing.
11. Support transmission with jack.
12. Remove front engine mounting capscrews.
13. Pull engine forward away from transmission and lift out of chassis.

1961-62 Six

1. Remove hood and radiator.
2. Remove fuel lines, vacuum lines, hoses, linkage and wires attached to engine units.
3. Disconnect power steering pump bracket and fasten pump in a position that will prevent oil from draining out.
4. Remove starter.
5. Remove automatic transmission fluid filler tube bracket and crankcase ventilation tube.
6. Disconnect exhaust pipe from exhaust manifold.
7. On cars with automatic transmission, support transmission and remove converter cover. Remove flywheel-to-converter bolts. Secure converter within housing to prevent it from being withdrawn as transmission is removed.
8. On standard transmission jobs, disconnect clutch and transmission linkage. Then slide transmission back far enough to clear flywheel housing and wedge it between floor pan and crossmember.
9. Unfasten engine mountings.
10. Remove rocker arm cover and attach a lifting rig to cylinder head. Then lift engine out of chassis.

1961-62 V8

1. Disconnect exhaust pipes from exhaust manifolds.

2. On standard transmission jobs, slide transmission rearward and support it with a block of wood wedged across frame crossmember.
3. On automatic transmission jobs, remove converter housing access cover. Remove four nuts securing converter to flywheel. Support transmission with a jack. Unfasten converter housing from cylinder block. Remove oil cooler bracket from cylinder block.
4. Remove starter, hood, battery carrier, radiator and power steering pump.
5. Remove fuel lines, vacuum lines, hoses, linkage and wires attached to engine.
6. Unfasten engine mountings. Then attach a lifting rig to engine and remove engine from chassis.

CYLINDER HEADS, REPLACE

1961-62 Six

1. Disconnect all linkage, wires, fuel and vacuum lines connected to cylinder head.
2. Remove air cleaner and radiator supply tank.
3. Remove rocker arm cover.
4. Remove capscrew and bracket from No. 6 rocker arm support and pull oil inlet line out of support and cylinder block.
5. Remove capscrew from No. 1 rocker arm support and remove oil outlet line and bracket.
6. Loosen all rocker arm adjusting screws to relieve valve spring load from rocker arms then remove rocker arm shaft assembly.
7. Remove valve push rods in sequence and identify them so they can be installed in their original positions.
8. Unfasten and pull manifold away from engine.
9. Unfasten and remove cylinder head.

V8-352, 383, 390, 430 engines. Note wedge-shaped combustion chamber formed in block and that underside of cylinder head is flat

10. Reverse removal procedure to install the head and tighten head bolts in the sequence shown in Fig 1 in three progressive steps. Make the final tightening to the torque given in the *Engine Tightening Specifications* chart.

Service Note

If a noise is encountered after a cylinder head is installed on six-cylinder engines, check for interference between push rod and push rod hole in cylinder head. If interference exists check

Engine lubrication. V8-352, 383, 390, 430 engines

Engine lubrication. V8-292 and 312 engines

V8-292 and 312 engines

straightness of push rod. If push rod is straight, then the cylinder head has not been properly aligned during its installation. The use of cylinder head guide pins (one at each end) during head installation will insure correct head alignment.

1955-62 V8

1. Drain cooling system.
2. Remove rocker arms and push rods.
3. Remove intake manifold.
4. Remove ignition coil from the left cylinder if that particular head is being removed.
5. Unfasten exhaust pipe from manifold.
6. Unfasten and remove cylinder head and exhaust manifold as a unit. *The exhaust manifolds should not be separated from the cylinder heads unless the head is to be replaced or the valves are to be ground.*
7. Reverse removal procedure to install either head and tighten head bolts in the sequence shown in Fig. 2 in three progressive steps. Make the final tightening to the torque given in the *Engine Tightening Specifications* chart.

Fig. 1 Cylinder head tightening sequence. 1961-62 Six

VALVES, ADJUST

Silent Valve Lash Mechanism, 1961-62 Six

As shown in Fig. 3, the rocker arm eccentric functions throughout the rocker arm motion during the valve opening and closing cycle, compensating for expansion or wear of the valve train. Therefore, solid contact, "silent lash" between all parts of the valve train mechanism is maintained.

After removal or replacement of rocker arm or associated parts, the eccentrics are to be adjusted to their operating position in two steps: First to an initial position and, second, to the final position. The initial position is accomplished with the engine shut off; the final adjustment is accomplished with the engine running at idle speed. Adjustments for noise complaints or "out-of-position" eccentrics require only the final adjustment procedure.

In making the initial adjustment, position each piston at approximately T.D.C. of compression stroke and adjust the two associated rocker arms as follows:

1. Remove rocker arm cover.
2. Adjust rocker arm by pushing eccentric toward rocker arm until plunger is completely into its rocker arm bore, Fig. 4. Turn adjusting screw in until eccentric and plunger are held in the depressed position.
3. Slowly turn adjusting screw out until adjustment mark on eccentric is centered over valve stem, Fig. 5, and lock jam nut. Correct position of adjustment mark is shown in Fig. 6.
4. Repeat foregoing adjustment on remaining rocker arms, bringing the piston of each cylinder up on its compression stroke so that both valves are closed.
5. After all rocker arms have been adjusted, start engine and operate at normal idle speed. Observe the position of the adjustment mark on each eccentric. Make minor adjustments as necessary with engine idling by turning adjusting screws in or out as necessary.
6. After adjustments have been completed, torque jam nuts to 35 ft. lbs., stop engine and install rocker arm cover.

V8-292, 312

Make three chalk marks on the vibration damper. Space the marks 90 degrees apart (¼ of circumference) so that with

Fig. 2 1955-62 V8 cylinder head tightening sequence

Fig. 3 Silent lash rocker arm operation. 1961-62 Six

Fig. 4 Aligning eccentric mark with valve stem. 1961-62 Six

Fig. 5 Depressing valve rocker arm eccentric. 1961-62 Six

Fig. 6 Correct position of eccentric. 1961-62 Six

the timing mark the damper is divided into four equal parts. Rotate the crankshaft until No. 1 piston is near TDC at the end of the compression stroke and adjust the following valves:

No. 1 intake and exhaust
No. 2 intake
No. 4 exhaust
No. 5 exhaust
No. 7 intake

Rotate the crankshaft 180 degrees (½ turn) which puts No. 4 piston on TDC. Then adjust the following valves:

No. 4 intake
No. 5 intake
No. 6 exhaust
No. 8 exhaust

Rotate the crankshaft 270 degrees (¾ turn), which puts No. 3 piston on TDC. Then adjust the following valves:

Fig. 7 Rocker arm shaft assembly. V8-292, 312

Fig. 8 Rocker arm shaft assembly. 1961-62 Six

No. 2 exhaust
No. 3 intake and exhaust
No. 6 intake
No. 7 exhaust
No. 8 intake

V8-352, 383, 390, 430

On these engines there is no provision for adjusting valve clearances. However, after a valve job, if the clearance between the rocker arm and valve stem does not have a clearance of .078″ to .218″ with hydraulic valve lifter collapsed .060″ shorter or .060″ longer push rods are available to reestablish the proper clearance. The shorter push rod is daubed with white paint and the longer one is daubed with yellow paint. If the measured clearance with hydraulic lifter collapsed is less than .078″, install a shorter push rod. If the clearance is more than .218″ install the longer push rod.

ROCKER ARMS

Sludge and gum formation in the rocker arms and shafts, Figs. 7, 8, 9 will restrict the normal flow to the rocker arms and valves. Each time the assemblies are removed (see *Cylinder Heads),* they should be disassembled and thoroughly cleaned.

Remove the support bracket bolts, cotter pins, washers, springs, support brackets and shafts. Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Inspect the shafts for wear. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When the assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves. The oil overflow pipe hole in the shaft should be seen through the center hole of the front support on the right bank and the rear support on the left bank. If the hole cannot be seen, turn the shaft until the holes line up.

Check each push rod for a bent or damaged condition. If bent more than .020″, when checked with an indicator, replace the push rod. Do not attempt to straighten a bent rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

VALVES, REMOVE

With the cylinder head removed as outlined previously, use a suitable valve spring compressor to compress each spring. Remove the valve locks and release the pressure on the spring. Remove the spring compressor and lift off the valve retainer, spring and valve. Repeat for the remaining valves. Keep the valves and related parts together so they may be installed in their respective positions if found in satisfactory condition.

VALVE GUIDES

Valve guides in these engines are an integral part of the cylinder head and, therefore, cannot be removed. For service, guides can be reamed oversize to accomodate one of three service valves with oversize stems (.003″, .015″, .030″).

Check the valve stem clearance of each valve (after cleaning) in its respective guide bore. If the clearance exceeds the service limit of .0045″ on the intake or .0055″ on the exhaust, ream the valve guides to accomodate the next oversize diameter valve.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long

Fig. 9 Rocker arm shaft assembly. V8-352, 383, 390, 430

enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 10. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 10 Checking installed height of valve spring

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}$″ to $\frac{5}{64}$″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Specifications* table within 10 per cent should be replaced. Likewise any spring that stands shorter than the new spring used for comparison should be discarded.

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{3}{64}$″, otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the block for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats, regardless of their condition.

The valve seat width after refacing should not exceed $\frac{1}{32}$″.

It is recommended that the fit of the valve in the valve seat be checked with a dial indicator for run-out, which should not exceed .0005″.

If a dial indicator is not available, a simple check of the fit of the valve in the valve seat may be made by spreading a thin film of Prussian Blue on the valve face and then inserting the valve. With hand pressure, rotate the valve ¼ turn, remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer of Prussian Blue will indicate an inaccurate valve and seat refacing operation.

VALVE LIFTERS

1957-62 Hydraulic

The internal parts of each hydraulic lifter assembly are a matched set. If these are mixed, improper valve operation may result. Therefore, disassemble, inspect and test each assembly separately to prevent mixing the parts.

Fig. 11 illustrates the type lifter used. See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method of locating a noisy valve lifter is by the use of a piece of garden hose about four feet long. Press one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it

Fig. 11 Hydraulic valve lifter disassembled

Fig. 12 Timing marks aligned for correct valve timing. V8-292, 312

Fig. 13 Timing marks aligned for correct valve timing. V8-352, 383, 390, 430

more than likely exists in all units.

To disassemble, first immerse the lifter in solvent and remove all traces of varnish and carbon. Remove the lock ring from the lifter body and disassemble as shown in Fig. 11. Wash all parts in solvent and wipe dry with lint-free cloth.

To assemble, hold the plunger inverted and assemble the valve disc, small spring, valve disc retainer, and large spring on the plunger. Slip the body over the plunger, then install the push rod cup and lock ring in the body.

TIMING CASE COVER

1961-62 Six

To remove front cover, remove radiator, radiator supply tank, fan, drive belt, pulley, vibration damper and water pump. Unfasten front cover from cylinder block and oil pan and remove cover. *If oil pan gasket is broken or damaged during front cover removal, drop the oil pan and install a new gasket.*

V8-292, 312, 352, 390

1. Remove oil pan.
2. Disconnect battery ground cable.
3. Remove radiator.
4. Remove power steering pump.
5. Remove drive belts.
6. Remove water pump and hoses as a unit.
7. Remove power steering pump pulley.
8. Remove vibration damper.
9. Remove fuel pump.
10. Remove front cover.

V8-383, 430

1. Remove oil pan.
2. Drain cooling system and remove radiator.
3. On cars with automatic transmission, disconnect and plug oil cooler lines from radiator.
4. Disconnect battery ground cable.
5. Remove power steering pump (if used) and mounting bracket from engine.
6. Remove generator and fan belt.
7. Remove water pump.
8. Remove fuel pump. Remove cup-type plug from top of cylinder front cover, using a punch and mallet. Then remove fuel pump push rod.
9. Remove vibration damper with suitable puller.
10. Unfasten and remove timing cover.
11. Install a new cover seal and reinstall cover in reverse order of removal.

TIMING CHAIN

V8-292, 312

When replacing a chain on these engines, insert a woodruff key in the keyway of the crankshaft and camshaft. Place the timing chain over the camshaft and crankshaft sprockets, making sure the timing marks are lined up adjacent to marks on timing chain, Fig. 12.

Holding the sprockets and chain in place, install on the camshaft and crankshaft at the same time. Take up the slack on the driving side of the chain by rotating the crankshaft and measure the chain deflection—which should not exceed ½" slack. Install the camshaft eccentric and counterweight as a unit. Align the keyway of the eccentric and counterweight with the woodruff key on the camshaft. Place the spacer in position and secure with a plain washer, lock washer and cap screw.

V8-352, 383, 390, 430

1. To remove the chain, first take off the timing chain cover as outlined previously.
2. Crank the engine until the timing mark on the camshaft sprocket is adjacent to the timing mark on the crankshaft sprocket, Fig. 13.
3. Remove cap screws, lock plate and fuel pump eccentric from front of camshaft.
4. Place a screwdriver behind the camshaft sprocket and carefully pry the sprocket and chain off the camshaft.
5. Reverse the foregoing procedure to install the chain, being sure to align the timing marks as shown.

Fig. 14 Valve timing. 1961-62 Six

Fig. 15 Piston and rod assembly. All V8's

1961-62 Six

To make the sprocket and chain accessible, remove radiator, vibration damper and front cover. Before removing crankshaft sprocket, align timing marks as shown in Fig. 14. Remove camshaft sprocket retaining bolt and washer. Slide chain and sprockets forward.

To install, place chain over crankshaft sprocket and insert camshaft sprocket into chain so timing marks on both sprockets are as shown in Fig. 14. Align keyway in camshaft with camshaft sprocket keyway and slide assembly into position.

CAMSHAFT, REPLACE

1961-62 Six

1. To remove camshaft, drain cooling system and oil pan.
2. Remove radiator, supply tank, grille and engine front cover.
3. Remove oil level dipstick, crankcase ventilation tube, stabilizer bar links, flywheel housing inspection cover and oil pan.
4. Remove rocker arm shaft assembly and push rods.
5. Remove distributor cap, valve push rod cover and fuel pump.
6. Remove timing chain and sprockets and distributor.
7. Raise valve lifters and secure them with spring-type clothes pins or window regulator clips.
8. Position crankshaft so that camshaft lobes will clear crankshaft counterweights.
9. Carefully remove camshaft from engine.

V8-292, 312

1. Remove hood.
2. On 1957 models, remove parking lamps without disconnecting wires,

grille upper mouldings and center grille moulding.
3. Remove rocker arm shaft assemblies, intake manifold and push rod cover.
4. Remove power steering pump.
5. Remove radiator and water pump.
6. Remove vibration damper. If equipped with power steering, its pulley must be removed from damper before removing damper.
7. Remove fuel pump and oil pan.
8. Remove timing chain and sprockets.
9. Raise valve lifters and hold them up with spring-type clothes pins.
10. Slide camshaft out of engine.

1961-62 V8-352, 390

1. Remove oil level dipstick.
2. Drain cooling system and oil pan.
3. Remove oil pan.
4. Remove center grille lower retaining bolts.
5. Remove radiator.
6. Remove radiator center grille.
7. Remove timing chain and sprockets.
8. Remove intake manifold and valve push rod chamber baffle.
9. Remove valve lifters, being sure to identify them so they can be installed in the original bores.
10. Slide camshaft out of engine.

1958-60 V8-383, 430

1. Remove the timing chain cover and chain as outlined previously.
2. Remove intake manifold.
3. Remove valve lifter cover.
4. Remove the hydraulic valve lifters and place them in a rack so they may be reinstalled in their respective bores. It may be necessary to remove the carbon from the top of the lifter bore before the lifters can be removed.
5. Remove grille.
6. Carefully slide camshaft out of engine.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

Fig. 16 Piston and rod assembly. 1961-62 Six

Fig. 17

PISTON & ROD, ASSEMBLE

Assemble the rod to the piston as shown in Figs. 16 and 17.

PISTONS

Pistons are available for service replacement in standard sizes and oversizes of .005", .020", .030" and .040".

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring. File the broken end to a sharp, square edge and use it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

New pistons should be fitted according to recommendations given in Fig. 17.

PISTON PINS

All (Except V8-383, 430)

It is recommended procedure to replace piston pins whenever new rings are installed. Pins that have been relatively quiet when the old rings were in service may be noisy after new rings are installed.

Use a suitable reamer to ream the piston for oversize pins. The pins are retained by snap rings, one located at each end of the pin. When installing the retainers, make sure each one enters the groove in the piston pin boss.

V8-383, 430

Pins are a press fit and no snap rings are used to retain them in place.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

Fig. 18 Checking bearing clearance with Plastigage

Fig. 19 Rotor type oil pump

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 18. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope, Fig. 18. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque figures given in the *Engine Torque Data* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

Fig. 20 Gear type oil pump

OIL PAN

1961-62 Six

1. Remove oil level dipstick and drain oil pan.
2. Unfasten stabilizer from lower suspension arm.
3. Remove left stabilizer clamp.
4. Loosen bolts securing right stabilizer clamp to frame side member. Pry stabilizer toward right, then pull stabilizer arms downward to allow clearance for removing oil pan.
5. Unfasten and remove oil pan, oil pump inlet tube and screen.

1961-62 V8's

1. For oil pan and crankshaft clearance purposes, crank engine to place No. 1 piston on top dead center (No. 6 on 292 engine). Remove oil level dipstick.
2. Drain oil pan.
3. Remove ends of stabilizer from mounting studs and pull the ends downward to allow clearance for oil pan removal.
4. On 292 engine, remove inlet tube from oil pump and loosen nut securing inlet tube to oil pan. Then unfasten and remove oil pan.
5. On 352 and 390 engines, unfasten and lower oil pan onto frame crossmember. Then reach into crankcase with a socket wrench and unfasten oil pick-up tube from oil pump. Allow screen and tube to drop into pan. Move pan forward and down to remove it from chassis.

1958-60 V8-383, 430

1. Crank engine to bring No. 1 piston at about 14° BTDC to obtain clearance between crankshaft counterbalances (refer to timing marks on vibration damper).
2. Disconnect battery ground cable.
3. Remove oil level dipstick.
4. On 1959-60 disconnect throttle linkage at plastic bushing at bellcrank.
5. Raise vehicle and drain oil.
6. Remove front engine support attaching nuts.
7. Position jack under front edge of oil pan. Lower vehicle enough to raise front of engine about 2″. Place 1″ block between each front engine support insulator and frame. Then raise vehicle and remove jack.
8. Unfasten stabilizer brackets from frame. Then disconnect either stabilizer link at lower suspension arm. Swing stabilizer down and outward to allow clearance for removal of pan.

9. Unfasten and lower oil pan to frame crossmember.
10. Unfasten oil pump tube and screen and allow to drop into pan.
11. Remove oil pan in a lowering forward motion.

1955-57 & 1958-60 V8-312

1. Bring No. 6 piston up on TDC to allow clearance between oil pan and crankshaft.
2. Remove screws attaching engine splash shield to frame side members.
3. Raise car and drain crankcase.
4. Unfasten and remove engine splash shield from frame crossmember.
5. Disconnect stabilizer and pull it forward to allow clearance for oil pan removal.
6. Remove inlet tube from oil pump and loosen nut securing inlet tube to oil pan.
7. Remove attaching screws and drop pan.

OIL PUMP REPAIRS

Rotor Type Pump, Fig. 19

1. With all parts clean and dry, check the inside of the pump housing and the outer race and rotor for damage or excessive wear.
2. Check the mating surface of the pump cover for wear. If this surface is worn, scored or grooved, replace the cover.
3. Measure the clearance between the outer race and housing. This clearance should be .006-.012″.
4. With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and housing. Measure the clearance between the straight edge and the rotor and outer race. Recommended limits are .0011-.0041″. *The outer race, shaft and rotor are furnished only as an assembly.*
5. Check the drive shaft-to-housing bearing clearance by measuring the O.D. of the shaft and the I.D. of the housing bearing. The recommended clearance limits are .0015-0029″.
6. Inspect the relief valve spring for a collapsed or worn condition.
7. Check the relief valve piston for scores and free operation in the bore. The specified piston clearance is .0015-.0029″.

Gear Type Pump, Fig. 20

After all parts are clean and dry, inspect the pump body and gear teeth for damage or wear. Check the gear end clearance with a dial indicator or Plastigage. The Plastigage method is as follows:

Position the gasket on the housing, then place a strip of Plastigage on the gears and install the cover. Remove the cover and check the Plastigage reading. The recommended clearance is .0015-.006″.

Check the gears for freedom of rotation. Inspect the relief valve spring for a collapsed or worn condition. Check the relief valve piston for scores and free operation in the bore.

Fig. 21 Oil and vacuum pump disassembled. 1958

1958 Oil-Vacuum Pump

1. Referring to Fig. 21, remove oil inlet pipe and screen from pump.
2. Disconnect vacuum inlet pipe from pump body.
3. Detach vacuum pump from oil pump.
4. Scribe a mark on cover plate and vacuum pump. Then remove oil pump cover plate and drive lug.
5. Remove vacuum pump eccentric and vanes as a unit, using a wire hook.
6. Remove vanes from rotor, and vane pin and spring.
7. Remove rotor and shaft from oil pump body.
8. Scrape the stake marks that secure the relief valve in the oil pump housing unit until the retainer can be removed together with spring and relief valve.
9. With all parts clean and dry, check the inside of the pump housing and the outer race and rotor for damage or excessive wear.
10. Check the mating surface of the pump cover for wear. If this surface is worn, scored or grooved, replace the cover.
11. Measure the clearance between the outer race and housing. This clearance should be .004-011″.
12. With the rotor assembly installed in the housing, place a straight edge over the rotor assembly and housing. Measure the clearance between the straight edge and the rotor and outer race. Recommended limits are .0015-.003″. *The outer race, shaft and rotor are furnished only as an assembly.*
13. Check the drive shaft-to-housing bearing clearance by measuring the O.D. of the shaft and the I.D. of the housing bearing. The recommended clearance limits are .0015-.0029″.
14. Inspect the relief valve spring for a collapsed or worn condition.
15. Check the relief valve piston for scores and free operation in the bore.

RADIATOR

1955-62

1. To remove the radiator, first drain the cooling system and disconnect upper and lower radiator hoses.

Fig. 22 Water pump. 6-223 engine

Fig. 23 Water pump. V8-352, 390

2. On cars equipped with automatic transmission, disconnect oil cooler inlet and outlet lines at the radiator.
3. Remove radiator support bolts and lift out radiator.
4. When installing the radiator on cars with automatic transmission, do not tighten the radiator support bolts until after the cooler lines have been connected.

WATER PUMP, REPLACE

1961-62 Six

1. Drain cooling system and disconnect hoses at water pump.
2. Remove fan, pulley and drive belt.
3. On power steering cars, remove power steering pump with hoses attached and place it in a position that will prevent fluid from draining out of reservoir.
4. Unfasten and remove pump from engine along with radiator supply tank.

1961-62 V8's

1. Drain cooling system and disconnect hoses from water pump.
2. Remove fan belt, fan, spacer (if equipped) and pulley.
3. On power steering jobs, remove power steering pump with hoses attached and place it in a position that will prevent fluid from draining out of reservoir.
4. Unfasten and remove water pump from engine front cover (292) or from cylinder block (352 and 390).

1958-60

1. Disconnect ground cable from battery.
2. Loosen and move generator toward engine to relieve tension on drive belts.
3. On air conditioned cars, loosen and move compressor inward to relieve drive belt tension. Remove power booster fan and take off compressor drive belt and pulleys.
4. On standard cars, remove fan, spacer and water pump.

1955-57

To remove the pump, drain the cooling system and take off the fan blades, drive belt and upper and lower hoses. Unfasten the pump from the engine front cover and lift it off.

WATER PUMP REPAIRS

1961-62 Six

1. When servicing the pump, refer to Fig. 22. Clean all gasket material from pump and back plate.
2. Install a new oil slinger on the new bearing and shaft assembly furnished with repair kit.
3. Apply a light film of waterproof sealer on the new seal and press seal into pump housing.
4. Coat bearing outer diameter with grease. Position the shaft assembly and press it into the housing until the outer face of the bearing is even with the outer face of the pump.
5. Position hub on shaft and press hub into place until the distance from the housing mounting face to the front face of the hub is 4 5/16".
6. Coat the impeller-to-seal rubbing surfaces with grease.

1961-62 V8-352, 390

1. When servicing this pump, refer to Fig. 23.
2. Position pump on an arbor press with hub end of shaft resting on a steel plate.
3. Press impeller onto shaft until it sets .070-.080" below back cover mounting face of pump housing.

Fig. 24 Water pump. V8-292, 312

Fig. 25 Water pump. V8-383, 430

Fig. 26 Ignition details. 1955-57 & 1958-62 V8-292, 312

Fig. 27 Ignition details. V8-352, 383, 390, 430

4. Press hub on shaft until it sets 8 $\frac{21}{32}$" from housing mounting face to front face of hub.

V8-292, 312

1. Referring to Fig. 24, coat the impeller seal rubbing surface with grease.
2. Install impeller on shaft and press downward until impeller-to housing clearance is .025-.035".
3. Coat new gasket on both sides with sealer and install on pump housing.

V8-383, 430

1. Referring to Fig. 25, support pump housing on hub end and insert seal with brass covered end down. Press seal into seat. Use sealer around edge of seat.
2. Support pump on arbor press. Position shaft and bearing assembly in pump with slinger facing downward.
3. Press shaft-bearing and slinger into housing until bearing is flush with hub edge of housing.
4. Press hub on shaft until a dimension of 6 $\frac{13}{32}$" is obtained between pulley mounting face of hub and mounting face of water pump legs.
5. Press impeller on shaft until rear flat face of impeller sets $\frac{7}{64}$" below back cover mounting face of pump housing.
6. Coat cover gasket with non-hardening type sealer and install gasket and back cover.

DISTRIBUTOR, REPLACE

1. To remove the distributor, disconnect the primary wire and vacuum control pipe. On some models the work may be made easier if the accelerator pull back spring is disconnected.
2. Remove distributor cap.
3. Scribe a mark on the distributor body indicating the position of the rotor, and scribe another mark on the body and engine block indicating position of distributor body in block. These marks can be used as guides when installing distributor in a correctly timed engine.
4. Remove hold down screw or screws and lift distributor out of block. *Do not crank engine while distributor is removed or the initial timing operation will have to be performed.*

Installation

If the crankshaft has not been disturbed, install the distributor, using the scribed marks previously made on the distributor body and engine block as guides.

If the crankshaft has been rotated while the distributor was removed from the engine, it will be necessary to retime the engine. Crank the engine to bring No. 1 piston on top dead center of its compression stroke. Align the timing mark on the vibration damper or pulley with the timing pointer (see *Tune Up* chart). Install the distributor so that the rotor points to the No. 1 spark plug wire terminal in the distributor cap, Figs. 26, 27.

IGNITION TIMING

Align the distributor rotor with No. 1 spark plug wire terminal in the distributor cap, when No. 1 piston is on the compression stroke and timing marks on the crankshaft pulley and pointer are aligned.

With the timing mark in line with the pointer, the distributor points should just start to open. It may be necessary to rotate the distributor body clockwise slightly and then counter-clockwise until the points just start to open. Tighten the distributor lock plate screw.

Start the engine and check the timing with a timing light.

Using Timing Light

When using a timing light, *be sure to disconnect the distributor vacuum line before checking timing,* otherwise the timing will be affected due to the fact that the vacuum opening is above the throttle plate.

Connect the timing light high tension lead to the No. 1 spark plug and the other two leads to the proper battery terminals. Clean the dirt from the timing mark and if necessary use white chalk to make the mark more visible.

Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark does not line up as the light flashes, rotate the distributor as required to bring them in alignment.

STARTER REPLACE

1955

1. Disconnect battery ground cable.
2. Raise car and remove front splash pan.
3. Remove cable from starter.
4. Unfasten idler arm support from frame. Lower support and idler arm assembly.
5. Remove capscrews holding end plate to converter housing.
6. Remove starter by pulling it out and down until starter drive clears housing.

1956

1. Disconnect battery ground cable.
2. Raise car and remove cable from starter terminal.
3. Remove capscrews securing starter drive end plate to flywheel housing.
4. Turn front wheels to full right position and remove starter by pulling out and down until starter drive clears housing.

1957

1. Disconnect battery ground cable and cable from starter terminal.
2. Disconnect ignition cable bracket under No. 4 spark plug.
3. Turn wheels full right and, after removing starter attaching screws, remove starter by pulling out and upward until starter drive clears housing. Continue upward movement of starter until it is in near vertical upright position between engine and fender apron with starter drive end facing down. While holding starter drive, rotate starter housing to allow clearance of drive end plate mounting bosses. Then lower starter between tie rod and idler arm.

1958

1. Turn front wheels to full right turn position.

2. Disconnect ground cable from battery.
3. Raise vehicle.
4. Remove cable from starter.
5. Remove both exhaust pipes from manifolds on cars equipped with single exhaust system. Remove right exhaust pipe on cars with dual exhaust.
6. Remove exhaust pipe from muffler.
7. Remove starting motor by pulling out and upward until starter drive clears housing. Continue upward movement until starter is in near vertical upright position between engine and fender apron with starter drive end facing downward.
8. While holding starter drive, rotate starter housing to allow clearance of drive end plate mounting bosses; then lower starter between tie rod and idler arm.
9. To install, reverse removal procedure. When installing the starter, be sure rubber seal is properly positioned to prevent misalignment or binding. Install three capscrews securing starter to flywheel housing. Tighten outer capscrew first; then tighten top and bottom screws. *If outer capscrew is tightened last, misalignment of starter with flywheel housing may result, causing starter motor failure.*

1959-62

1. Disconnect battery ground cable.
2. Disconnect throttle linkage at bellcrank.
3. Raise vehicle.
4. Remove cable from starter terminal.
5. Remove engine splash shield from front crossmember.
6. Remove front engine support insulator nuts.
7. Place jack under front edge of engine oil pan (protect with wood block) and raise engine about 1".
8. Unfasten starter from flywheel housing (3 capscrews).
9. Starter can then be removed by lowering it between tie rod and steering idler arm (drive end down).
10. Install in reverse order of removal, being sure rubber seal is properly positioned to prevent misalignment or binding.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Do not use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

CARTER CARBURETOR ADJUSTMENTS

Fig. ①—AFB float level. Adjust by bending float lever.

Fig. ②—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ③—Measure from top of bowl cover to top of plunger shaft with throttle connector rod in inner hole in pump arm. Adjust by bending throttle connector rod.

CARTER NOTES

METERING ROD

WCFB—Metering rod adjustment must be made after pump adjustment. With throttle valves fully closed, loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

④—With engine at normal operating temperature, turn fast idle screw against low step of fast idle cam until specified rpm is obtained.

Fig. ⑤—With throttle wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. Adjust by bending unloader lip on throttle lever.

Fig. ⑥—ABD float level. Adjust by bending lip on float arm.

Fig. ⑨—With throttle wide open, there should be the clearance specified between upper edge of choke valve and air horn wall. Adjust by bending tang on choke unloader lever.

Fig. ⑦—Measured from top of pump plunger to top of bowl cover. Adjust by bending throttle connector rod.

Fig. ⑧—With engine at normal operating temperature, turn fast idle screw against high step of fast idle cam until specified rpm is obtained.

CARTER NOTES
continued

⑩—With throttle closed and hot idle screw against its stop, loosen dashpot locknut. Hold dashpot plunger in to the limit of its travel. There should be the clearance specified between plunger and throttle operating lever. Rotate dashpot in its bracket to obtain desired clearance.

⑪—With primary throttle valves wide open, there should be the clearance specified from top of bowl cover to top of dashpot plunger. Adjust by bending stop lug on flat lever.

FORD NOTES

Fig. ①—Float level measured from top surface of main body to top of free end of float with float in uppermost position.

②—With fast idle screw on high step of cam.

③—Open throttle plates halfway. Hold choke plate closed by means of choke housing shaft. Clearance between cast stop on back of choke housing and edge of fast idle cam should be as listed. To adjust, loosen bellcrank lever screw and turn lever as required to obtain correct clearance.

④—Hold secondary throttle plates closed. Turn secondary throttle shaft lever screw out until the plates stick in the throttle bores and there is the clearance listed between screw and throttle lever. Then turn screw in one full turn.

⑤—With engine at normal operating temperature and hot idle speed properly adjusted, loosen dashpot locknut. Hold throttle closed and depress plunger. Clearance between throttle lever and plunger should be as listed. To adjust, turn dashpot in its bracket as required.

⑥—Pump lever has four holes and pump link has two holes to control pump stroke. Install pump rod in top hole for winter operation, and second hole from bottom for summer operation. Install pump operating rod in outside hole in pump link.

⑦—With choke plate fully closed, adjust bellcrank lever so that fast idle stop screw seats on next to highest step on fast idle cam.

⑧—Turn fast idle speed screw in until it just touches the lowest step on the fast idle cam, then back off ¼ to ½ turn.

⑨—For standard transmission set on Index; for automatic transmission set 2 notches lean.

⑩—Clearance between fast idle cam and stop with choke plate closed and throttle plate ¼ open should be as listed. To adjust, position bellcrank lever on choke housing shaft as required.

HOLLEY NOTES

Fig. ①—Float level measured from floor of float bowl to bottom of float with bowl inverted. Adjust as outlined in note ⑤.

②—With throttle fully closed, hold dashpot plunger in to the limit of its travel. Then turn adjusting screw as required to obtain the clearance specified between end of screw and plunger.

③—Turn fast idle adjusting screw in until it just touches lowest step on fast idle cam.

④—With throttle fully closed and dashpot plunger held in to the limit of its travel, there should be the clearance listed between plunger and throttle lever. Adjust by rotating dashpot in its bracket as required.

⑤—With engine running at hot idle speed, remove plug (both plugs on 4-bore units) from sight hole. If fuel just dribbles out of sight hole, fuel level is correct. If not, adjust float level on 1959 and later units by loosening lock screw on top of bowl and rotate adjusting nut as required. On 1957-58 models, adjust float level internally by bending tab on float lever.

⑥—With throttle plates closed, there should be the clearance listed between unseated bowl vent valve and vent valve seat. Adjust by bending vent arm of accelerating pump lever (not valve rod).

⑦—Below machined surface of float bowl.

HOLLEY CARBURETOR ADJUSTMENTS

HOLLEY NOTES continued

⑧—With primary throttle plates held wide open, there should be the clearance listed between pump arm and hex nut on accelerating lever with pump held fully depressed. To adjust, hold hex nut and turn adjusting screw as required.

⑨—With fast idle screw on highest step of fast idle cam.

⑩—See Fig. ①. Primary ¾", secondary ½".

⑪—See Fig. ①. Primary 11/16", secondary 9/16".

Fig. ⑫—Float level measured from machined surface of float bowl.

⑬—With engine running at hot idle speed, loosen dashpot screw. Hold throttle closed and depress dashpot plunger fully. Turn dashpot in its bracket as required to obtain the specified clearance between plunger and accelerator lever.

Fig. ⑭—Float level measured from roof of float chamber to lowest point of float with carburetor inverted.

Fig. ⑮—Fuel level measured from power valve mounting surface.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

To check the clutch pedal free play, depress the clutch pedal by hand and measure the distance the pedal travels before the beginning of clutch disengagement is felt. The free travel should be ¾" to 1". If the travel is not within these limits, adjust as follows:

Loosen the clutch pedal release rod lock nut and turn the adjusting nut until the free pedal travel is within the above limits. Tighten the lock nut to secure the adjustment.

CLUTCH SERVICE

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may

be replaced without special equipment.

1955-56

If the clutch facings become worn to the extent that clutch pedal free travel cannot be adjusted to the correct limits, the clutch assembly should be removed and the clutch disc replaced. The clutch or disc may be removed as follows:

Remove the transmission as outlined further on. Slide the clutch release bearing and hub assembly off the end of the clutch release lever. Disconnect the clutch pedal release rod from the release lever assembly.

Remove the clutch release equalizer bar bracket from the flywheel housing and the equalizer bar. Remove the split bronze bushing from the bracket.

On all models, remove the flywheel housing. Prick-punch the flywheel and clutch cover so that at assembly these parts may be installed in their original position. Loosen the clutch-to-flywheel attaching screws a turn or two at a time until clutch pressure spring load is relieved. Then remove the screws and take the clutch from the flywheel.

1957-62

After removing the transmission as outlined further on, disengage clutch pedal retracting spring from clutch release lever. Unfasten equalizer bracket from flywheel housing. Remove flywheel housing cover. Unfasten clutch from flywheel and remove.

TRANSMISSION, REPLACE

Drain the transmission. Disconnect gearshift linkage at the transmission. Remove speedometer cable and gear. Remove propeller shaft and necessary exhaust pipes. Unfasten the transmission extension from the engine rear support. Place a jack under the engine to relieve its weight, then remove the frame crossmember and engine rear support.

Unfasten the transmission from the clutch housing. Install two guide pins in the upper holes. Slide the transmission to the rear until the main drive gear clears the clutch housing. Then lower the transmission and pull forward to remove it from the vehicle.

When removing transmissions equipped with overdrive, be sure first to disconnect the overdrive control cable and solenoid and governor wires and remove the governor.

TRANSMISSION REPAIRS

The following describes the procedure for units without overdrive. For detailed service on the overdrive, consult the *Overdrive* chapter. To disassemble the transmission, see Figs. 1 and 2 and proceed as follows:

1. Remove gearshift housing.
2. Drive out the pin that retains the countershaft and idler gear shaft to the transmission case (prior to 1955).
3. Unfasten the extension housing and twist it ¼ turn counterclockwise to permit removal of countershaft. Drive countershaft out the rear of case, using a cluster gear roller retainer shaft tool or a spare countershaft cut to the length of the cluster gear. Leave cluster gear and dummy shaft in case until after main drive gear and mainshaft have been removed. Remove extension and mainshaft assembly from case.
4. Drive reverse idler shaft out of case and lift out reverse idler gear.
5. Unfasten and remove main drive gear bearing retainer.
6. Tap main drive gear out through front of case.
7. To disassemble mainshaft, remove snap ring that holds it to the extension housing. Tap mainshaft out of extension. Remove snap ring from in front of synchronizer and strip mainshaft of all parts.
8. After cleaning and inspecting parts, reassemble transmission by reversing the order of the foregoing procedure.

Fig. 3 Standard transmission interlock linkage. 1962

SYNCHROMESH GEARSHIFT, ADJUST

1962

1. Referring to Fig. 3, disconnect interlock shift rod at interlock shift lever at transmission.
2. With clutch pedal properly adjusted, place selector lever in neutral.
3. Loosen two bolts that attach interlock wedge to lever. Position wedge so that it fully enters notch of low and reverse shift lever. Tighten wedge attaching bolts.
4. Attach interlock shift rod to shift lever. Make sure that clutch pedal is fully released (clutch engaged) and tighten interlock shift rod adjusting nut at interlock shift lever.

1958-61

The gearshift rods are adjusted so that with the transmission gears in neutral, the two levers on the steering column are in line with each other. In this position, the shift lever can be moved up and down in neutral without binding.

When adjusting the rods, disconnect them from the steering column linkage and loosen the lock nuts. Turn the clevises in the direction required to establish the correct adjustment.

AUTOMATIC TRANS.

Replace, 1961-62

1. Disconnect linkage and oil cooler lines from transmission.
2. If equipped, disconnect vacuum tube from vacuum diaphragm and pressure test line.
3. Remove converter housing-to-engine upper bolts.
4. Remove starter motor upper bolt from right side of engine.
5. Remove converter housing lower plate.
6. Drain converter and transmission.
7. Remove drive shaft.
8. Remove converter-to-flywheel nuts.
9. Remove starter.
10. Support transmission with jack.
11. Remove engine rear support bolts.
12. Remove crossmember (it may be necessary to disconnect and lower exhaust pipes on dual exhaust jobs to provide clearance).
13. Remove converter housing-to-engine lower bolts and remove transmission and converter.
14. Reverse foregoing procedure to install.

Replace, 1960

When removing the transmission on cars with V8-312 engine, follow the procedure outlined for previous models. However, on cars equipped with V8-383 and V8-430 engines, the transmission gear box cannot be removed without also removing the torque converter and converter housing. To increase rigidity, two additional bolts are used to attach the converter housing to the case. These

Fig. 4 Throttle control linkage adjustment. 1955

Fig. 5 Throttle linkage adjustments. 1956-57

additional bolts are located at the rear of the converter and are not accessible in the vehicle.

Replace, 1955-59

1. To remove the transmission only, first drain fluid.
2. Disconnect linkage from transmission.
3. Disconnect speedometer cable from transmission.
4. Remove drive shaft after disconnecting rear universal joint.
5. Unfasten rear engine mount from frame cross member.
6. Support engine and transmission with separate jacks.
7. Remove rear engine mount from transmission.
8. Remove detachable cross member from frame X member.
9. Unfasten transmission from converter housing (4 bolts).
10. Pull transmission straight back and out.
11. Reverse foregoing procedure to install.

1955 Throttle Linkage

1. Referring to Fig. 4, set the hand brake and adjust the engine idle at 425-450 rpm with transmission in Drive range.
2. Disconnect clevis at point "C" and insert gauge pin through shaft and bracket.
3. Set carburetor at low idle at point "A".
4. Adjust carburetor-to-transmission control shaft rod so that goes in freely at point "A". If too long, shorten one turn and assemble at "A".
5. Remove gauge pin.

Fig. 6 Manual selector cable adjustment. 1958 automatic transmissions

Fig. 7 Park release cable adjustment. 1958 automatic transmissions

Fig. 8 Throttle linkage adjustment. 1958 automatic transmissions

6. Holding carburetor arm in low idle position ("A") pull upward on transmission control-to-accelerator rod. This positions transmission control outer lever in stop position at transmission. Adjust clevis at point "C" so that clevis pin enters clevis and lever freely. Lengthen rod by turning clevis three full turns counterclockwise and assemble in place.

1955 Manual Adjustment

1. Referring to Fig. 4, disconnect clevis at point "1".
2. Position manual lever at point "1" so pointer at steering wheel is against stop in "DR" position.
3. Position manual lever at transmission at point "2".
4. Adjust manual shift rod so that clevis pin enters the hole freely. Then lengthen rod by turning clevis one full turn.
5. Check position of selector pointer at all positions on dial.

1956-57 Throttle Linkage

Before starting this procedure, set hand brake and adjust engine idle to 425 rpm with engine and transmission at operating temperature and lever in Drive range. Adjust the anti-stall dashpot by turning the throttle lever set screw out until the dashpot plunger bottoms, then backing off to give .045" - .065" clearance at point "Y" on Fig. 5. Then proceed as follows:

1. Disconnect clevis at point "C" as shown in Fig. 5.
2. Disconnect carburetor to transmission control shaft rod at carburetor.
3. Insert gauge pin through bellcrank and bracket in transmission control to accelerator shaft assembly at point "D".
4. Set carburetor arm at low idle manually.
5. Adjust carburetor to transmission control shaft rod so that with trunnion pin in place at point "B" trunnion pin at carburetor end will go in freely.
6. With gauge pin locking bellcrank, pull upward gently on transmission control shaft to transmission rod assembly. This will position the throttle lever in the stop at the transmission.
7. Adjust clevis at point "C" so the clevis pin enters the clevis and lever on transmission control to accelerator shaft assembly.
8. Then, lengthen transmission control shaft to transmission rod assembly by turning clevis 3 full turns counterclockwise and assemble in place.
9. Remove the gauge pin.

1956 Manual Adjustment

1. Referring to Fig. 5, disconnect transmission manual shift rod assembly from transmission control selector arm assembly at point "1".
2. Position the manual lever at point "1" so the pointer at the steering wheel is against the stop in Drive position.
3. Position transmission manual control lever so it is in the second position from the bottom at point "2".
4. Adjust transmission manual shift rod so the clevis pin enters the hole freely, then lengthen the rod by turning the clevis one full turn.
5. Check position of pointer at all stations on the dial.

1957 Manual Linkage

1. Depress L button until it latches.
2. Raise car and attach detent selector cable to transmission by pushing cable downward into selector cable guide hole in transmission case. Selector cable retainer spring is most easily engaged when the low gear selector button is depressed. Test to find if retainer spring is engaged by pushing upward on cable. The cable cannot be removed if retainer spring has engaged.
3. Attach control cable mounting bracket to groove in cable casing. Install bracket retaining bolt and washer *finger tight*.
4. Move mounting bracket and cable upward to limit of slot travel in mounting bracket. Rotate Park Lever counterclockwise against "LO" stop in case. Hold Park Lever in this position and tighten screw to insure correct position of "LO" detent.
5. Torque bracket bolt 18-22 lb. ft.

1957 Park Release Cable

1. After selector cable has been adjusted, depress N/S button until it latches. *Tape the park slide fully back in the pull out position.*
2. Route the park release cable through retaining clip at transmission, leaving clip retainer screw loose enough so that cable can be adjusted forward or back. Pull cable core lightly toward rear of car to remove slack.
3. With N/S button in latched position, rotate park release lever counterclockwise to its neutral stop position. Hold lever in this position and adjust park release cable so that the hole in the cable aligns with pin in lever. Then attach park release cable to park release lever.
4. Tighten screw and bracket. Attach retracting spring to park lever pin.
5. With engine running and transmission at normal operating temperature, push all of the buttons and note whether the desired ratios are obtained.

1958 Manual Selector Cable

1. Raise car, remove splash shield and pipe plug from left side of transmission case.
2. Remove park release control cable from lever and clamp.
3. Loosen control cable mounting bracket retaining screw and washer leaving it finger-tight).
4. On Merc-O-Matic, hold Drive button on transmission keyboard selector in the fully depressed position. On Multi-Drive, hold Cruising range button in fully depressed position.
5. Move adjusting bracket downward to limit of travel.
6. Install tool shown in place of pipe plug in transmission case, Fig. 6.
7. Pull upward on selector cable and housing assembly until pin in gauge seats in locating slot of selector cable connector sleeve (see insert in Fig. 6).
8. Leaving tool in place, torque control cable mounting screw to 18-22 lb. ft.
9. With gauge installed, pull gauge pin out and hold out so selector cable connector sleeve will clear. Depress the "Neutral Start" button and release the gauge pin so it contacts connector sleeve. Now depress "Drive" button and check to see that gauge pin seats in the locating slot

Fig. 9 Throttle linkage adjustments. 1959

in the selector cable connector sleeve. Release the gauge pin and depress the "Drive" button. If the gauge pin fails to seat in the slot the selector cable must be readjusted.

10. Remove gauge and replace pipe plug.

1958 Park Cable, Adjust

A correct park release cable adjustment cannot be obtained until proper selector cable adjustment is completed.

1. Install park cable on the pin of the park release lever and install clamp and screw on adjusting bracket.
2. Fully depress park bar on keyboard selector.
3. On small transmissions, install Gauge 77270-E over torsion lever support pin in transmission case and the pin on the park release lever as shown in Fig. 7. On large transmissions, use Gauge 77270-G.
4. Remove cable slack by pulling cable housing toward rear of car.
5. Holding cable in this position, tighten cable clamp screw.
6. Remove gauge tool.
7. Install washer and retaining pin in park release lever pin.
8. Check operation of all selector buttons and the park bar.

1958 Throttle Linkage, Adjust

1. Referring to Fig. 8, adjust toggle rod for shortest overall length.
2. Attach one end of rod to accelerator shaft and other end to transmission control shaft.
3. Measure distance between bottom surface of accelerator pedal and bare floor pan. This distance should be 4 inches.
4. To raise pedal to required height, lengthen the rod; to lower pedal, shorten rod.
5. After pedal height is adjusted, have someone depress accelerator pedal to floor while a check is made to see that the "kickdown" mechanism is properly adjusted. This is determined by watching for additional movement of the transmission control shaft after the throttle is fully opened. The added movement of the shaft will cause the pin to override the full throttle position in the slot

Fig. 10 Throttle rod adjustments. 1959

Fig. 11 Mercomatic manual linkage. 1959

Fig. 12 Multi-drive manual linkage. 1959

in the transmission control-to-accelerator shaft assembly. If kickdown is not obtained, lengthen rod slightly.

1959-60 Linkage

Linkage adjustments must be made in the sequence which follows: First, however, engine idle speed must be adjusted to 450-475 rpm with manual lever in "D" position for Mercomatic or "D2" for Multi-Drive. Be sure anti-stall dashpot has the proper clearance as given in the carburetor tables.

1959-60 Carburetor Rod

1. Referring to Fig. 9, insert a ¼" drill at point "D" through bellcrank bracket and tab.
2. Hold carburetor lever against hot idle screw and adjust rod between points "A" and "B" so pin enters carburetor lever freely.
3. Assemble carburetor rod and remove ¼" drill.
4. Recheck engine idle rpm with retracting spring tension applied and readjust if necessary.

1959 (Only) Toggle Rod

1. Referring to Fig. 9, adjust toggle rod for shortest overall length.
2. Attach one end of rod to accelerator shaft and the other end to transmission control shaft.
3. Measure distance between bottom surface of accelerator pedal and bare floor pan. This distance should be $4\frac{3}{16}$". Lengthen rod to raise pedal or shorten rod to lower pedal.
4. Now have someone depress accelerator to floor while a check is made to see that the "kickdown" mechanism is properly adjusted. This is determined by watching for additional movement of the transmission control shaft after the throttle has fully opened. The added movement of the shaft will cause the pin to override the full throttle position in the slot in the transmission control-to-accelerator shaft (refer to point "E").
5. If kickdown is not obtained, lengthen toggle rod slightly.

1959-60 Throttle Rod

1. Raise car and install pressure gauge at rear of transmission. Then lower car.
2. Pull upward on throttle rod firmly but gently, Fig. 10. Adjust clevis at point "C" so that clevis pin enters freely. Lengthen clevis 3½ turns on 383 and 430 engines or 2 full turns on 312 engines. Then reassemble throttle rod.
3. Start engine and with foot brake firmly set, place selector lever in "D" for Mercomatic or "D2" for Multi-Drive.
4. Accelerate engine to 1000 rpm. Pressure gauge reading should be 80-85 psi. To correct the pressure, adjust length of throttle rod. Lengthen clevis to increase or shorten clevis to decrease pressure. *These checks must be made quickly. The selector must be returned to neutral position and the throttle closed after each check to avoid overheating the transmission.*
5. Remove pressure gauge.

1959-60 Manual Linkage

1. Referring to Figs. 11 and 12, disconnect manual rod clevis at point "1".
2. Position selector lever at point "2" so that pointer is against the stop in drive range. This position must be held throughout the manual adjustment.
3. Position detent lever at point "1" in second position from bottom (drive detent).
4. Adjust manual rod clevis so that clevis pin enters clevis and detent lever freely. Lengthen clevis one full turn and reassemble.
5. Check position of pointer in each drive range. If pointer is off location, adjust position of letters. *Do not adjust linkage* to correct pointer alignment in the other ranges.

MANUALLY-CONTROLLED THROTTLE LINKAGE

Early 1961

Carburetor Rod, Adjust

1. Referring to Figs. 14, 15 and 16, disconnect transmission throttle rod at its upper end (this step not required on Multi-Drive).
2. Disconnect carburetor rod at carburetor lever.
3. Insert ¼" gauge pin through gauge pin holes in bellcrank bracket and tab.
4. While holding carburetor lever against hot idle adjusting screw, adjust length of carburetor rod for a free fit into carburetor lever. *Then lengthen carburetor rod one turn.*
5. Remove ¼" gauge pin and connect carburetor rod.
6. Recheck alignment of gauge pin holes in bellcrank and tab. Further adjustment of carburetor rod may be required as the ¼" gauge alignment holes must be in alignment to assure correct carburetor-to-transmission calibration.

Throttle Rod, Adjust

Refer to Figs. 13, 14 and 15, and disconnect throttle rod at upper end. Pull upward on throttle rod firmly but gently. Adjust throttle rod link so stud freely enters hole in bellcrank. Lengthen link 3½ turns and reconnect throttle rod. *This is a preliminary adjustment only. Final setting must be made with pressure gauge to assure adequate pressure for proper clutch and band application. See Automatic Transmission Chapters for pressure testing procedures.*

Accelerator Pedal Height, Adjust

Referring to Figs. 13 and 16, measure distance from top of accelerator pedal to floor mat. This measurement must be approximately 3½". Road test car and check transmission "kickdown" operation. If "kickdown" cannot be obtained or if it occurs too early, shorten or lengthen the accelerator link as required.

Fig. 13 Throttle linkage for 1961 Six

Fig. 14 Throttle linkage for 1961 V8 with two-speed Mercomatic

Fig. 15 Throttle linkage for 1961 V8 with three-speed Mercomatic

Fig. 16 Throttle linkage for 1961 Multi-Drive

VACUUM-CONTROLLED THROTTLE LINKAGE

Late 1961 & 1962 Two-Speed Trans.

V8-292 and 352 Engines: Referring to Fig. 17, apply parking brake and place selector lever in "N". Then adjust as follows:

1. With engine at normal operating temperature, adjust idle speed to 485 rpm.
2. With throttle in hot idle position, bottom dashpot plunger and adjust dashpot so there is $\frac{9}{64}$" clearance between plunger and throttle lever shaft.
3. With engine stopped, disconnect carburetor connecting link from accelerator.
4. Insert a ¼" drill rod through gauging holes shown at "A", Fig. 17. Hold carburetor connecting link forward and adjust sleeve until link assembly fits freely in accelerator assembly. Then rotate sleeve counterclockwise one full turn. Remove drill rod.
5. If accelerator pedal height is not 3½", measured as indicated at "C", Fig. 17, adjust threaded trunnion on accelerator pedal link until correct height is obtained.

6-223 Engine:

1. Measure accelerator pedal height at 'C", Fig. 17 (top view). If not 3¾", turn threaded trunnion on accelerator connecting link as required.
2. Disconnect downshift control rod from bellcrank.
3. Block accelerator pedal to floor.
4. Push downshift control rod down to the limit of its travel. Then adjust sleeve on rod until end of rod enters bellcrank freely. Connect linkage and tighten lock nut.

Fig. 17 Vacuum-controlled throttle linkage. Late 1961 and 1962 two-speed transmission

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

1957-62 REAR AXLE

This rear axle, Fig. 1, is a banjo-housing hypoid in which the drive pinion is mounted below the centerline of the ring gear. The drive pinion is straddle-mounted in that two opposed tapered roller bearings support the pinion shaft at the front of the pinion gear and a straight roller bearing supports the pinion shaft at the rear of the pinion gear.

The pinion shaft and gear are assembled to the pinion retainer which is bolted to the carrier housing. Two carrier and differential cases are used to accomodate two bearing sizes.

Axle Shaft, Remove

Take off wheel and unfasten brake drum from axle shaft flange. Through hole provided in flange, remove nuts that secure brake support plate to axle housing. Then with a suitable puller pull shaft out of housing. Use care not to dislodge the brake support plate or damage the oil seal in the housing. Install one nut to hold brake plate in position.

Axle Shaft Bearing, Replace

Axle shaft bearings should be removed only when necessary to install a new bearing. A bearing once removed should be discarded.

To replace a bearing, loosen axle shaft bearing retainer ring and remove retainer. The bearing may be removed with

a bearing puller, after which remove retainer plate.

To install, place retainer plate on shaft. Press bearing up against shoulder on shaft. Install bearing retainer ring and press it firmly against bearing. Before installing shaft, examine oil seal and replace if necessary.

Oil Seal, Replace

Before installing a new oil seal it should be soaked for at least 30 minutes to make it soft and pliable. When installing a seal, use a suitable seal driver, driving the seal into the axle housing and tight against the shoulder. When installed, check outer diameter of seal for tightness in housing to avoid possible leaks.

Axle Shaft, Install

Remove temporary nut holding brake plate, and lubricate bearing bore in housing. Clean brake plate surface and install new gaskets between retainer plate and brake plate. Slide axle shaft into housing, using care not to damage oil seal. Push shaft in until its bearing is tight against shoulder in housing. Tighten axle shaft nuts to a torque of 30-35 ft. lbs. and install brake drum and wheel.

Rear Axle, Remove

It is not necessary to remove the entire rear axle assembly to service the differential carrier assembly. After removing propeller shaft and axle shafts, unfasten differential carrier from axle housing and remove carrier from housing.

Drive shaft and universal joints

Rear Axle Repairs

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, are given in the *Rear Axle Chapter*.

The following service procedure is significant for this type axle.

Disassembly

1. Mark one differential bearing cap and bearing support to ensure proper assembly. Remove adjusting nut locks, bearing caps and adjusting nuts. Lift differential out of carrier.
2. Remove drive gear from differential case.
3. Drive out differential pinion shaft retainer and separate the differential pinion shaft and remove gears and thrust washers.
4. Remove drive pinion retainer from carrier. Remove O-ring from retainer.
5. Remove pinion locating shim. Measure shim thickness with micrometer.
6. If the drive pinion pilot bearing is to be replaced, drive the pilot end and bearing retainer out at the same time. When installing, drive the bearing in until it bottoms. Install a new retainer with the concave side up.
7. Mount the drive pinion retainer assembly in a holding fixture and

Fig. 1 Exploded view of 1957-62 rear axle. (4 pinion differential also used)

Fig. 2 Rear axle. 1955-56

remove pinion shaft nut and flat washer. Then remove universal joint flange, oil seal and slinger.

8. Remove pinion retainer from fixture and place a protective sleeve or hose on the pinion pilot bearing surface. Then press the pinion shaft out of front bearing cone and remove spacer.
9. Remove pinion rear bearing cone.
10. Do not remove pinion bearing cups from retainer unless they are worn or damaged. The flange and pilot are machined by locating on these cups after they are installed in the bores. If new cups are to be installed, make sure they are seated in the retainer by trying to insert a .0015″ feeler gauge between cup and bottom of bore.

Assemble Carrier

Differential Case—Place a side gear and thrust washer in the differential case bore. *Lubricate all parts liberally with axle lubricant during assembly.* With a soft-faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear. Place the second pinion and thrust washer in position. Drive the pinion shaft into place. Be careful to line up pinion shaft retainer holes. Place second side gear and thrust washer in position and install differential case cover. Install retainer. A pinion or axle shaft spline can be inserted in side gear spline to check for free rotation of differential gears.

Insert two $\frac{7}{16}$″ x 2″ bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning the drive gear bolt holes. Press or tap the drive gear into position. Install and tighten the drive gear bolts evenly and alternately across the gear to 60-65 lb. ft. torque.

If the differential bearings have been removed, use a suitable press to install them.

Assemble Pinion

Pinion and Retainer—Install the pinion rear bearing cone on the pinion shaft and install a new spacer on the shaft. Place the bearing retainer on the pinion shaft, then install the front bearing cone. *As the bearing is pressed into position, rock the pinion retainer. Do not press the bearing on the shaft until all play is removed between retainer and bearings as the spacer may be compressed too much.*

Lubricate both bearings with axle lubricant. Place oil slinger in position. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the bearing retainer. New seals need not be soaked before installation. Install the universal joint flange. Place the flat washer over the pinion shaft and start the pinion shaft nut.

Hold the flange and tighten the pinion shaft nut until a torque required to turn the pinion is 8-12 *inch* lbs. with used bearings or 17-27 *inch* lbs. with new bearings. As the pinion shaft nut is tightened, rotate the pinion shaft frequently to allow the bearing to seat.

Pinion, Adjust

Shim Selection — Manufacturing tolerances in the pinion bore dimensions and in the best operating position of the gears make an adjustment shim necessary. This shim is placed between the pinion retainer and the carrier, Fig. 1. An increase in the thickness of the shim moves the pinion *away* from the drive gear. Manufacturing objectives are to make axles requiring a .0015″ shim and if a new assembly is being built, a .0015″ shim should be used for a tentative build-up. Shims are available in .010″ to .021″ thicknesses in steps of .001″.

Pinions and drive gears are marked, when matched, with the same number. Following the number on the pinion is a minus (—) or plus (+) followed by a number. If the pinion is marked "—1" it indicates that a shim .001″ thinner than a standard shim for this carrier is required. A minus number means the pinion should be moved closer to the drive gear and a thinner shim is required. A plus number means the pinion should be moved farther from the drive

gear and a thicker shim is required. A pinion marked zero (0) is a standard pinion.

To select a shim, measure the original shim with a micrometer. Note the dimensional mark on the original pinion. Compare the mark on the original pinion with the mark on the new pinion to determine how the original shim should be modified.

For example, if the original shim is .015″ and the original pinion is marked "—1", the new pinion requires a +1 shim. Therefore, the new pinion requires a .002″ thicker shim, and a .017″ shim should be used. If the new pinion is marked the same as the old pinion, no shim change is required.

1955-56 REAR AXLE

In this type axle, Fig. 2, the drive pinion is held in position by shoulders in the differential carrier, upon which the pinion bearing cups seat. The pinion position is maintained by shims located between the rear bearing and the rear shoulder in the differential carrier. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The shimmed type of differential bearing adjustment is employed. The procedure for making this adjustment, as well as the assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

The axle tubes are pressed into the differential carrier to form a one-piece housing. To overhaul the unit, therefore, the rear axle assembly must be removed from the chassis.

Pinion & Bearings, Replace

After removing the axle shafts and differential unit, unscrew the pinion flange retaining nut and pull off the flange. The pinion may then be removed from the carrier by driving it out of the front bearing with a brass drift and hammer. After the pinion is free of the front bearing, pull it out through the rear of the carrier.

Mount the pinion in a press and press the pinion shaft out of the bearing. When replacing the bearing select a suitable sleeve or length of pipe of the same diameter as the cone so the rollers or cage will not be damaged when being forced on the shaft.

Drive the front bearing cup and oil seal out of the forward end of the carrier. If the rear bearing cup is to be replaced or if the pinion setting is to be changed, remove the rear bearing cup.

To change the pinion setting, the shims behind the rear bearing cup should be measured with a micrometer. The necessary shims may then be removed or added to obtain the proper pinion setting as indicated when a pinion setting gauge is used (see *Rear Axle* Chapter). After the required shims have been added or subtracted, replace the rear bearing cup.

When making a pinion adjustment, the same thickness of pinion bearing adjusting shims should be added or removed at the rear bearing cup to retain the proper pinion bearing adujstment.

To install the pinion, support it under the head with a wood block while the pinion flange is reinstalled. The pinion oil seal should not be replaced until after the pinion setting has been checked.

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearing are tight, but still permit rotating the pinion by hand.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion may be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle* Chapter. If a correction is necessary, disassemble the pinion and, if it is to be moved toward the center of the axle, add shims between the rear bearing and rear shoulder in the carrier. If the pinion has to be moved away from the center of the axle, remove shims from this point.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle* Chapter. After satisfactory tooth contact has been established, remove the pinion flange to install the seal.

Axle Shaft, Replace

The procedure for replacing an axle shaft, bearing and oil seal is the same as outlined for 1957 and later models.

POWER BRAKE UNIT, REPLACE

1960-62

Remove master cylinder outlet fitting from cylinder. If only the brake booster is to be removed, support the master cylinder with a prop from the underside. This eliminates the necessity of disconnecting the outlet fitting and consequently bleeding is not required during assembly.

Remove vacuum hoses. Unfasten and remove master cylinder. Remove power brake unit from bracket on dash panel (4 capscrews) and remove power brake.

1959

1. Working in engine compartment, remove master cylinder outlet fitting bolt. *It is not necessary to remove stop light switch, wires or tube from fitting. Do not disturb master cylinder outlet fitting.*
2. Remove vacuum hose from power unit.
3. Remove vacuum reserve tank hose from fitting.
4. Working inside car under instrument panel, remove capscrew and locknut securing push rod to brake lever.
5. Remove power brake from bracket on dash panel.
6. Install in reverse order of removal and bleed system in the conventional manner.

1955-58

1. Working inside the car under the instrument panel, disengage valve push rod from brake pedal.
2. Working in engine compartment, remove master cylinder outlet fitting bolt from master cylinder. *It is not necessary to remove the stop light switch, wires or hose assembly from the outlet fitting. Do not disturb the outlet fitting.*
3. Remove manifold vacuum hose from check valve on power unit.
4. Remove vacuum reserve tank hose from fitting on check valve.
5. Unfasten power brake assembly (4 screws) from bracket on dash panel.
6. To install, reverse foregoing procedure. Then bleed brakes in the usual manner. After bleeding, fill hydraulic brake reservoir to within ¼″ of the top of filler cap opening and replace cap.

BRAKE MASTER CYLINDER, REPLACE

1960-62

1. Working inside passenger compartment, remove eccentric bolt, bushing and lock nut that secures master cylinder push rod to brake pedal. Remove push rod and bushing from pedal.
2. Remove hydraulic outlet fitting.
3. Remove stop light switch.
4. Unfasten master cylinder from dash panel (2 capscrews).
5. Reverse above procedure to install and bleed hydraulic system.

1955-59

To remove the master cylinder, take off the eccentric bolt, bushing and lock nut that secures the master cylinder push rod to the brake pedal from inside the passenger compartment. Remove the hollow bolt attaching the stop light switch and hydraulic line outlet fitting to the master cylinder. Unfasten the master cylinder (4 bolts) from the engine side of the dash panel.

Reverse the order of removal to install the master cylinder and bleed the hydraulic system as directed in the *Brakes* chapter.

Front End and Steering Section

CAMBER & CASTER, ADJUST

1955-56

To adjust caster, loosen the two bolts that secure the upper suspension arm shaft to the frame and insert shims between the shaft and frame. A $\frac{1}{16}$" shim at the front bolt will produce a *negative* caster of ½ degree. A $\frac{1}{16}$" shim at the rear bolt will produce a positive caster of ½ degree. Shims are available in thicknesses of $\frac{1}{64}$", $\frac{1}{32}$", $\frac{1}{16}$" and ⅛". When the correct adjustment is obtained, torque the bolts to 75-80 lbs. ft. Caster must be held within ½ degree difference on both sides.

Camber is also adjusted at the upper suspension shaft. To adjust, insert or remove the shims from between the shaft and the frame at both the front and rear bolts. Each $\frac{1}{16}$" shim removed will add ¼ degree of positive camber. The camber must be the same on both sides within ¼ degree.

1957-58

While the front suspension is fundamentally the same as 1956 the fact that the upper control arm inner shaft is bolted to the outer surface of the frame bracket affects wheel alignment adjustments.

Loosen the two bolts that secure the upper control arm to the frame and adjust caster and camber as follows:

Caster—A $\frac{1}{16}$" shim added at the rear bolt will add a *negative* caster of ½ degree. A $\frac{1}{16}$" shim added at the front bolt will add a *positive* caster of ½ degree.

Camber — To adjust camber, insert or remove shims at both the front and rear bolts. Each $\frac{1}{16}$" of shim added will give ¼ degree of *positive* camber. Each $\frac{1}{16}$" of shim removed will give ¼ degree of *negative* camber.

1959-60

Front wheel alignment is accomplished without the use of shims. Alignment is performed by movement of the upper control arm shaft. The holes in the upper control arm shafts are oversize, permitting them to be moved as required for correct camber and caster adjustment.

To adjust caster and camber, two ¼" x 1½" bolts with nuts are required to be inserted in the frame bracket holes as shown in Fig. 1. The upper control arm shaft nuts are then loosened and the shaft moved to obtain the adjustment. Fig. 1 illustrates the results that can be obtained by moving the shaft. *When the adjustment is correct, torque the control arm shaft bolts to 100-110 lbs. ft. Proper torquing of these bolts is essential to insure that the alignment will not change during vehicle operation.*

1961-62

Caster—To adjust caster, loosen the two bolts that secure the upper suspension arm shaft to the frame and insert or remove shims as required between shaft and frame.

A $\frac{1}{16}$" shim added at the front bolt will change caster ½° in the positive direction. A $\frac{1}{16}$" shim removed from the front bolt will change caster ½° in the negative direction. When caster is correct torque bolts to 65-85 ft. lbs.

Camber—To adjust camber, insert or remove an equal number of shims from between the upper suspension arm shaft and frame at both the front and rear bolts. Each $\frac{1}{16}$" of shim will change camber ¼°.

TOE-IN, ADJUST

Position the front wheels in the straight-ahead position. Then turn both tie rod adjusting sleeves an equal amount until the desired toe-in setting is obtained.

WHEEL BEARINGS, ADJUST

1955-60

Tighten spindle nut with a 12-inch

TURNS OF FRONT BOLT	APPROXIMATE CHANGE IN CASTER

1	¼°
2	½°
3	¾°
4	1°
5	1¼°
6	1½°

Fig. 1 Caster and camber adjustments. 1959. For 1960, use 5/16" bolt instead of ¼" indicated

wrench while rotating wheel back and forth until there is a noticable drag or bind. This assures that the bearing cones are properly seated. Then back off the spindle nut to line up with the nearest cotter pin hole that will allow the hub to rotate freely with no perceptible end play. Lock the spindle nut in this position with a cotter pin.

1961-62

While rotating the wheel, torque the retaining nut to 11-14 ft. lbs. Then back off the nut at least one full castellation but less than two and install the cotter pin.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check the joints for wear as follows:

A method of checking friction load on upper joints by means of a torque wrench is provided. After separating the upper joint from the steering knuckle, the joint stud nut is installed and tightened on the stud. The stud is then turned in its socket with an inch-pound torque wrench. The torque should range from 20 to 35 inch pounds. If reading is below 20, replace the joint.

To check lower joint, jack up under the frame rather than under the lower control arm to maintain the coil spring load on the lower joint. Then grasp the tire at top and bottom and move it in and out. If movement at edge of tire exceeds ⅛", ball joint is worn and should be replaced.

FRONT SUSPENSION

1961-62

The front suspension, Figs. 2 and 3, is quite similar to that used in 1958, the chief difference being that threaded metal bushings are used in the upper control arm shaft instead of the rubber type used in 1958. In Fig. 3, note that the front suspension lower arms are attached to the frame front crossmember through a shackle and rubber bushing arrangement.

1959-60

This suspension, Fig. 4, is similar to 1958 except that a different method of adjusting caster and camber is employed (see Fig. 1). Note that the shim type of caster and camber adjustment has again been adopted in 1961.

1957-58

As shown in Fig. 5, the front suspension is fundamentally the same as 1956. However, the suspension arms are one-piece metal stampings. They are secured to the frame and crossmembers in the same manner as prior models but the upper control arm shaft is secured to the outer surface of the frame bracket in place of the inner surface.

The ball joints are riveted to the control arms. These joints can be replaced by using a ⅜" drill to remove the old rivets. The new ball joints are then secured to the control arm with ⅜-24 x 2" bolts furnished in the ball joint kit.

The control arm bushings are removed and installed in the same manner as in 1956. The shock absorbers are basically the same as prior models but the upper mounting utilizes a one-piece rubber bushing as an insulator between the frame and shock absorber.

All other front suspension operations are performed in a similar manner to that of the 1956 suspension.

Fig. 2 Front suspension. 1961 "600" Series

1955-56

This suspension, Fig. 6, is the ball joint type. It differs from other types of suspension in that the wheel spindle is attached directly to the suspension arms by means of ball joints located at the outer ends of both arms. The conventional steering knuckle, knuckle support and kingpin is eliminated.

The working parts of this type suspension are assembled directly to the vehicle frame and cannot be removed as an assembly. However, individual parts may be replaced as outlined below.

Shock Absorber

To remove a shock absorber, unfasten it from the frame at its upper end. Remove the two cap screws that retain the shock absorber mounting plate to the lower control arm and lower the shock absorber unit.

To install, reverse the removal procedure and tighten the two lower cap screws to 13-18 lbs. ft. torque.

Lower Arm & Spring, Remove

Raise the front of the car and place a support stand under each frame side rail to the rear of the lower control arm. Remove the hub cap and pry off the grease cap. Remove the nut from the wheel spindle and pull off the wheel assembly with hub and brake drum.

Remove the shock absorber as outlined

Fig. 3 Front suspension. 1961-62 (except "600")

above and detach the stabilizer (stabilitor) bar from the lower control arm.

Loosen the slotted nut which attaches the lower ball joint stud to the lower spindle boss one or two turns. Then with a brass bar and hammer, strike the lower spindle boss to pop the stud loose against its nut. Place a jack under the outer end of the lower arm and raise the jack until the upper arm rebound bumper is clear of the frame. The nut can then be removed and the spindle and brake assembly lifted off the ball joint stud and moved out of the way.

Lower the jack until the coil spring is free and can be removed. Note the rubber insulators at the upper and lower ends of the spring.

Unfasten the lower control arm from the frame and remove the arm. Inspect the bushings on the inner end of each arm leg and replace if defective.

When installing bushings, do not attempt to press them beyond the edge of the shoulder ribs as severe distortion will result, which will affect the operation of the suspension unit. Under no circumstances should only one bushing be replaced.

Ball Joint Service

Remove the cover and seal from the ball joint. Inspect the joint and replace if found defective. If the joint is still serviceable, *do not* wash it in solvent as it will be extremely difficult to lubricate it again. Do not hammer the ball joint bodies as binding will result. Inspect the metal seal parts for damage and replace if necessary. Replace the sponge rubber seal, making sure it is stuffed into the metal seal cup before pushing it down over the ball joint stud.

Lower Arm & Spring, Install

To install the lower control arm, secure the rearward leg to the frame crossmember tube, running the nut up finger tight. With the arm forced firmly against the tube, install enough shims to fill the space between the forward arm leg bushing and front crossmember. Then install the bolt and washers and run the nut up finger tight. With the arm in curb load position (approximately horizontal) with the outer end slightly lower than the inner, tighten the nuts to 80-100 lbs. ft. torque.

Place the coil spring with the rubber insulators in position on the lower control arm. Then with a jack under the lower arm, compress the coil spring. Care must be taken to see that the upper and lower ends of the spring are properly seated and the rubber insulators are in place. Guide the spindle boss over the ball joint stud. Install the nut and torque it to 100 lbs. ft. Continue to tighten until the cotter pin holes are lined up and install the cotter pin.

Remove the jack from under the arm and install the shock absorber. Secure the stabilizer bar to the lower suspension arm.

Upper Arm, Remove

Remove the shock absorber. Place a jack under the lower control arm spring seat and raise it until some of the tension has been removed from the upper bumper. Remove the wheel and tire assembly.

Wire the spindle to the frame to avoid possible damage to the brake hose from undue tension. Loosen the ball joint stud by backing the nut off one or two turns and striking the spindle boss. Remove the stud nut completely and then remove the two bolts that secure the inner shaft to the frame. Note the number of shims between the shaft and frame at each of the bolt locations. Then take off the upper control arm.

When installing bushings, be sure to use a spacer tool of the proper dimensions between the arm legs so that the arm will not be distorted or bent. When both bushings are in place, install the nut and washer on each end of the shaft and tighten finger tight. Position the shaft in the arm so that the shaft bolt holes are parallel with the arm. Then tighten the nuts from 80-100 lbs. ft. torque. Under no circumstances should only one bushing be replaced.

Note—The upper ball joint is serviced in exactly the same way as the lower.

Upper Arm, Install

Position the arm on the frame crossmember. Use the same number of shims that were originally used between the shaft and frame bracket. Secure the shaft to the bracket with the two bolts and torque the bolts to 75-80 lbs. ft. Place the ball joint stud in the spindle boss, install the nut and tighten it to 80 lbs. ft. minimum. Continue to tighten until the cotter pin holes are lined up and install a cotter pin.

Install the wheel and hub assembly and remove the jack from under the lower control arm. Finally, check the wheel alignment as previously outlined.

HORN SOUNDER & STEERING WHEEL

1959-62

Remove horn ring emblem by turning counterclockwise. Remove steering shaft nut and, with suitable puller, remove horn ring and steering wheel.

When installing, align mark in steering wheel hub with mark on steering gear shaft.

1958

The horn ring is removed in the same manner as outlined for 1959 except that the horn ring emblem is pried from the column head with a screwdriver.

1955-57

Remove the emblem from the steering column head by rotating the emblem counterclockwise with the palm of the hand. Remove the steering shaft nut and, with a suitable puller, remove the steering wheel and horn ring.

Reverse the foregoing operations to install the wheel and ring and torque tighten the wheel nut 60-70 lbs. ft.

STEERING GEAR, REPLACE

1959-62

1. Disconnect steering shaft from gear at flexible coupling.
2. Raise car and remove pitman arm.
3. Loosen manifold outlet clamp and hanger at forward end of muffler.
4. Remove manifold outlet pipe (on dual exhaust jobs, remove crossover pipe and left hand outlet pipe only).
5. Unfasten steering gear from frame and remove.

1958

1. Disconnect battery ground cable.
2. Remove pitman arm.
3. Loosen three bolts securing steering gear to frame. *If shims are used between gear housing and frame, mark bolt holes where these shims are used.* Also mark shims in such a manner that they may be returned to the same location.
4. Unfasten exhaust pipe from manifold.
5. Remove air cleaner and intake duct.
6. Remove exhaust manifold.
7. Remove No. 8 spark plug.
8. Remove steering wheel.
9. Disconnect electrical connections for turn signal and horn.
10. Disengage accelerator pedal from its push rod and pivot pedal toward rear.
11. On cars with manual shift transmission, disengage shift arms from shift rods and push rods toward center of car. Also remove back-up light switch.
12. Remove steering column cover plates attaching parts. Remove left plate and slide right plate back along speedometer cable.
13. Remove steering column opening seal.
14. Unfasten steering column bracket.
15. Remove steering gear through opening in dash panel.

Fig. 4 Front suspension. 1959-60

1955-57

1. Remove clamp that secures reservoir hose to fitting on brake booster cylinder (if equipped).
2. Remove clamp that secures reservoir hose to dash panel. Move hose away from steering column opening in dash panel.
3. Remove steering wheel.
4. Disconnect steering column electrical connections.
5. Remove accelerator pedal from accelerator push rod.
6. Remove clutch and brake pedals.
7. Pull floor carpeting away from dash panel opening.
8. Remove insulator and floor opening cover plates.
9. Unfasten steering column bracket from instrument panel and pedal support bracket.
10. Disconnect shift rods from steering column shift arms.
11. Loosen clamp on lower steering column at steering gear housing. Raise column sufficiently to disconnect wires at neutral switch on Merc-O-Matic models only. Remove steering column tube from steering shaft through inside of vehicle.
12. Raise front end of car and remove nut securing pitman arm to steering gear shaft. Then pull off pitman arm.
13. *Loosen* three bolts that secure steering gear assembly to frame side rails. *Remove shims, if any, located between mounting bolts and frame side rail. Mark bolt holes and number of shims required to facilitate assembly. Mark shims for identification with bolt holes.*
14. With one man in passenger compartment and another under the vehicle, remove the three bolts previously loosened and lift the steering gear out through the passenger compartment.
15. Reverse the order of the foregoing procedure to install the unit.

Fig. 5 Exploded view of front suspension. 1957-58

MANUAL STEERING GEAR, ADJUST

1955 & Early 1956, Fig. 7

Before proceeding with the adjustments, loosen the gear housing from the frame side rail to relieve any possible vertical strain. Loosen the steering column clamp to relieve any possible horizontal strain. Then tighten the mounting and clamp bolts which will relieve any misalignment in the steering gear mounting.

Steering gear adjustments must be made in the order given below to insure satisfactory results.

Worm Bearing Preload

The worm bearing preload is controlled by the shim pack installed between the steering gear housing and the housing upper cap. The shim pack contains shims of various thicknesses; the thinner shims are installed on the top of the pack, and the adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Turn the steering wheel two complete turns from the straight-ahead position. Hook a spring scale to the steering wheel rim. Rotate the wheel at least one turn with the aid of the scale. The pull required to keep the wheel moving should be between ⅛ and ⅝ lbs., which is the worm bearing preload. If the reading is high, a shim or shims should be added. If reading is too low, remove a shim or shims.

If an adjustment is required, unfasten the upper cap from the housing and work the cap and column jacket upward to allow clearance for removing or adding shims. For additional working clearance it may be necessary to remove the steering wheel.

To add a shim, split the shim at one point and install the shim with the split in the upward position. Make sure the split ends do not overlap as this could lead to a false adjustment.

To remove a shim separate the first shim from the pack with a knife blade. Pass the blade all around the shim, being careful not to damage the shims.

The steering column and upper housing cap must be assembled on the gear housing each time the preload is checked.

Worm & Roller Mesh

This adjustment is controlled by the adjustment screw mounted on the sector shaft cover. Adjustment is made as follows:

Disconnect the sector shaft arm from the steering linkage. Attach a spring scale to the steering wheel rim. Pull the wheel through the straight-ahead position and note reading on scale. The scale reading should be at least ½ lb. above that of the worm bearing preload previously determined, but the total reading must not exceed 1⅝ lbs. If the scale read-

Fig. 6 Ball joint front suspension. 1955-56

ing does not exceed the worm bearing preload by at least ½ lb., the worm and roller mesh should be adjusted.

Place the steering wheel in the straight-ahead position. Remove the adjusting screw cover and lock washer. Rotate the adjusting screw clockwise while moving the steering gear arm back and forth until all backlash is removed.

Install the lock washer and cover and check the preload with the spring scale as previously described. The reading should be between 1 and 1⅝ lbs. If the reading is too high, turn the adjusting screw slightly counterclockwise. If too low, turn the screw slightly clockwise.

STEERING GEAR REPAIRS

Worm & Ball Nut Type

1. Rotate steering worm until nut is in center of travel, Fig. 8.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Fig. 9 Worm and ball nut type steering gear. 1956-62

Fig. 7 Exploded view of steering gear. Worm and roller type, 1955-56

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined below:

Adjustments

1. Disconnect steering relay rod from pitman arm.

Fig. 10 Power steering system. 1955-62

2. Loosen sector shaft lash adjuster screw a few turns to relieve load from bearings.
3. Turn steering wheel in one direction until stopped by gear, then back away about one turn.
4. With a spring scale hooked to rim of steering wheel, measure pull required to keep wheel in motion; this should be ¼ to ¾ lbs. on a 9″ radius. If not within these limits, adjust worm bearings as follows:
5. Loosen worm bearing adjuster lock nut and turn adjuster until there is no perceptible end play in worm. Check pull at wheel rim, readjusting as required to obtain proper pull. Tighten lock nut and recheck pull.
6. After worm bearing adjustment is completed and all mounting bolts tightened, adjust sector shaft end play.
7. With steering wheel in straight-ahead position, turn lash adjuster screw clockwise to remove all lash and tighten lock nut.
8. Check pull at rim of steering wheel, taking highest reading on scale as wheel is turned through the central or straight-ahead position. This should be between ⅞ and 1½ lbs. *If more than 1½ lb., turn lash adjuster screw counterclockwise, then come up on the adjustment in a clockwise motion.*
9. Tighten lock nut and recheck pull.

Worm & Roller Type Disassemble, Fig. 8

1. Drain lubricant from housing.
2. Remove sector shaft and cover.
3. Remove cover from sector shaft.
4. Unfasten and slide housing cap off steering shaft.
5. Pull shaft out of housing.
6. Slide housing upper cap gaskets (shim pack), bearing cup, and upper worm bearing out of housing.
7. Use suitable puller to remove lower worm bearing cup.
8. Press sector shaft needle bearings and oil seal through steering arm end of housing.

Inspect & Assemble

After cleaning all parts, inspect worm and rollers for scores, cracks or for signs of chipping. Inspect steering shaft bearing cups and bearings for wear, cracks or damage. Check sector shaft for wear at needle bearing locations. Replace all parts that are damaged enough to impair steering gear operation, and assemble the steering gear in the reverse order of disassembly.

POWER STEERING, 1955-62

There are two items in the power steering system which require periodic maintenance. First, the oil level in the reservoir should be checked at 2000-mile

Fig. 11 Power steering rotor type pump

intervals. If fluid is below the oil level mark on the reservoir, add automatic transmission fluid as required. Second, check belt tension periodically. If any adjustment is made, turn wheels full right and left several times. Then, with the engine at idle check the fluid level. Before installing the cover on the reservoir, be sure there are no air bubbles in the fluid.

On Car Adjustments

Adjustment of belt tension and bleeding of the system are the only two "on the car" adjustments which can be made.

Belt Tension

There are two methods by which belt tension can be checked: Using a hook gauge, apply 5 to 7 lbs. upward force. Measure deflection of belt. If the deflection is ¼", adjustment is unnecessary. In the absence of a gauge, the wheels may be turned full right or left to the wheel stop to determine whether the pump stops or the belt squeals. In either case, adjustment is necessary.

To adjust the belt tension, loosen the belt pivot and adjusting bolts on the pump mounting bracket to allow movement of the bracket in its adjusting slot. To tighten the belt, hold pump body in hand and raise (do not lift assembly by the reservoir). Secure the setting by tightening pivot and adjustment bolts enough to hold. Recheck the belt deflection and, if satisfactory, torque the pivot bolt to 20-25 lb. ft. Tighten adjusting bolt.

Bleeding System

Belt Driven Pumps—To bleed the system, raise front wheels and run engine at idling speed until normal operating temperatures are obtained. Then accelerate the engine and turn front wheels to right and left several times until bubbles in reservoir disappear. *Do not hold wheels against stops.* Always recheck and replenish fluid in reservoir after bleeding.

Fig. 13 Roller type power steering pump

Crankshaft Driven Pump—Fill reservoir and bleed system as follows: Run engine at idling speed. *Do not steer the wheels.* When all foam is free from reservoir (inspect with light), rotate steering wheel from stop to stop to remove air from steering gear. Refill reservoir to full mark, replace cover and check system for leaks.

Fig. 12 Power steering vane type pump

PUMP, REPLACE

1955-57

1. Remove cover and drain reservoir with a suction gun.
2. Disconnect hose at fitting on pump and tube on reservoir. Secure hose and tube in raised position to prevent further drainage from system.
3. Remove pump drive belt.
4. Remove pump, reservoir and bracket as a unit. If the pump is to be serviced, refer to Fig. 11.
5. Reverse removal procedure to install the pump and adjust belt tension as outlined previously.

Fig. 14 Power steering control valve assembly

6. Fill reservoir to proper level and bleed the system as outlined above.

1958-60 Removal V8-383, 430

1. To remove the pump, take off hood.
2. Remove radiator and hoses.
3. If so equipped, remove air conditioning condenser, condenser inlet lines and receiver.
4. Loosen generator adjusting strap and belts.
5. Drain power steering system and disconnect hydraulic fittings.
6. Remove vibration damper.
7. Unfasten and slide pump from front end of crankshaft. If pump does not slide easily off shaft, use a suitable puller, utilizing the two tapped holes in the pump cover.
8. If the pump is to be disassembled, refer to Figs. 12 and 13.

1958-60 Installation V8-383, 430

1. Wipe crankshaft clean of any foreign matter. Replace key if damaged or worn.
2. Install rubber grommets in pump housing. All holes except bottom left rear accommodate one-piece grommets. Bottom left hole uses a two-piece grommet.
3. Slide pump on shaft. Inspect pressure and return hoses for cleanliness and for condition of flares and threads. Install hose ends in pump and torque nuts to 20-25 lb. ft. Pressure hose should not touch body sheet metal because of sound transmission.
4. Tighten pump mounting bolts to 10-13 lb. ft.
5. Insert woodruff key in shaft, place pulley on shaft and secure with washer and bolt. Torque to 80-100 lb. ft.
6. Tighten generator adjusting strap and belt.
7. Install radiator and hoses. On cars with air conditioning, install condenser inlet line, receiver and condenser.
8. Install hood.
9. Fill reservoir and bleed system as outlined previously.

CONTROL VALVE, REPLACE

1. Remove reservoir cover and drain fluid with a suction gun.
2. Raise car and drain remaining oil in system by disconnecting valve-to-cylinder lines at valve. Turn wheels to right and left several times to insure complete drainage.
3. Disconnect lines from cylinder. Then remove index pin from steering arm rod.
4. Loosen sleeve clamp bolt.
5. Remove pitman arm from control valve ball stud.
6. Lift control valve and ball stud clear of pitman arm and turn pitman arm out of the way.
7. Twist control valve off connecting link.
8. If the control valve is to be disassembled, refer to Figs. 14 and 15.

Upon reassembly of control valve, be sure to install the valve spool with the large diameter end toward the small end of the valve housing.

Installation

1. Screw control valve onto connecting link until approximately four threads are showing on link rod.
2. Install ball stud in pitman arm.
3. Before installing the ball stud nut on models prior to 1961, measure the distance from the center of the ball stud to the center of the tie rod ball stud (on 1961, measurement is taken from center of tie rod ball stud to center of lubrication fitting plug in the control valve sleeve). The distances are as follows:

1955-56	9"
1957-58	11¼"
1959-60	9⅜"
1961-62	11 15/16"

4. Align slot in sleeve with hole in connecting link and install indexing pin.
5. Torque sleeve clamp bolt to 22-28 lb. ft.
6. Install and torque ball stud nut to 40-50 lb. ft.
7. Install hydraulic line. Torque all fittings except inlet pressure line to 20-30 lb. ft.
8. Check centering of steering wheel and make any necessary adjustment of tie rods to properly center wheel.
9. Check toe-in and adjust if necessary.
10. Fill pump reservoir and bleed system.
11. Verify wheel pull with 15 pound scale. If the installation is satisfactory, 7 to 12 lbs. pull will be required to activate the system, assuming that the car is on dry concrete and engine is running at idling speed.

POWER CYLINDER

Removal

1. Drain fluid from reservoir with a suction gun.
2. Raise car and drain remaining fluid by disconnecting valve-to-cylinder hoses at cylinder. To insure complete drainage, move wheels to left and right several times.
3. Remove nut which secures piston rod to mounting bracket on frame. Remove cup washer and rubber bushing.
4. Remove palnut and nut which secures cylinder to stud on connecting link. Remove cup washer, rubber bushing and cylinder.

Fig. 15 Power steering control valve sleeve assembly

5. Remove rubber bushings and cup washers from end of piston rod and from connecting link stud.
6. Inspect all bushings and washers for wear and replace those parts which are worn or damaged.

Installation

1. Place cup washer and rubber bushing on piston rod. Insert rod of piston through hole in frame bracket, then place cup washer and bushing on connecting link stud. Install end of cylinder on connecting link stud.
2. Place second bushing and cup washer on connecting link stud. Install nut and torque to 50-65 lb. ft. Install palnut finger tight plus ⅓ turn. *Be sure nut is tightened until it bottoms.*
3. Place second rubber bushing and cup washer on piston rod end of frame, torque attaching nut to 40-50 lb. ft.
4. Install valve-to-cylinder lines. Short line in forward hole in cylinder, and long line in rear hole of cylinder.
5. Fill reservoir and bleed system.

Instruments, Radio and Windshield Wiper

INSTRUMENT CLUSTER

1955-56

1. Disconnect battery cable to prevent accidental short circuit.
2. Unfasten steering column from instrument panel and pull steering column down as far as possible to provide clearance for cluster removal.
3. Remove four nuts from back of instrument cluster and two Phillips screws from front of cluster (at the top).
4. Pull cluster forward, disconnect wires from gauges and remove speedometer (or any other instrument as required).

1957 Except Turnpike Cruiser

1. Disconnect battery ground cable.
2. Remove two screws at top rear of cluster.
3. Remove two screws in right and left instrument cluster.
4. Lift cluster straight up from instrument panel. Disconnect speedometer cable and remove all lamps from rear of cluster.

1957 Turnpike Cruiser

1. Disconnect battery ground cable.
2. Remove three screws at top rear of speedometer cluster.
3. Remove four screws just ahead of heater controls.
4. Remove average speed computer and clock.
5. Remove screw from top and inside computer and clock panel housing.
6. Remove tachometer.
7. Remove screw at top and inside tachometer panel housing.
8. Remove turn signal sockets and bulbs.
9. Pull speedometer cluster out far enough to enable removal of generator and oil pressure indicator lamp socket and bulb.
10. Remove other sockets and bulbs.
11. Disconnect computer drive cable and speedometer cable.
12. Remove speedometer and instrument cluster.

1958

1. Disconnect battery ground cable.
2. Remove steering wheel.
3. Mask steering column tube and area around speedometer and instrument cluster to avoid scratching the finish.
4. Unfasten speedometer and instrument cluster hood (4 screws) from dash panel.
5. Remove instrument cluster hood.
6. Remove windshield wiper knob and shaft.
7. Unscrew wiper control retaining nut.
8. Pull speedometer and instrument cluster out slightly to facilitate removal of both turn signal sockets and bulbs, high beam indicator socket and bulb, generator indicator and oil pressure indicator sockets and bulbs, and instrument lamp socket and bulb.
9. Remove light switch shaft and knob by pushing switch shaft straight in and releasing shaft spring pin retainer; remove lock nut and switch.
10. Disconnect speedometer cable.
11. Disconnect wiring from terminals on fuel gauge, temperature gauge and voltage regulator.
12. Remove speedometer and instrument cluster.

1959-60

1. Disconnect battery ground cable.
2. Remove two screws securing hood and speedometer assembly to instrument cluster.
3. Raise hood and speedometer assembly upward off dowel pins and disconnect cable.
4. Disconnect speedometer lamp wiring at four-way connector and remove speedometer and hood assembly.

1961-62

In order to remove the speedometer, the upper instrument cluster must be taken out after which the speedometer can be removed. To remove the upper instrument cluster, proceed as follows:

1. Disconnect battery ground cable.
2. Disconnect speedometer cable.
3. Remove wires from clip at right hand clock retaining nut.
4. Release instrument cluster wire loom from two clips.
5. Protect upper cluster and steering column from damage with cloth.
6. Remove automatic transmission quadrant dial cover moulding.
7. Place transmission selector lever in low gear position.
8. Remove ten upper cluster-to-instrument panel retaining screws. Four long screws at top, four screws at bottom and two screws just above steering column.
9. Turn automatic transmission indicator to one side.
10. Carefully pull upper cluster outward and lay it on protective cloth on steering column.
11. Remove wiring harness and clips. Disconnect gauge wires, remove sockets and lamps and remove cluster.

RADIO REMOVAL

1957

1. Disconnect battery ground cable.
2. Disconnect speaker and antenna leads from radio.
3. Disconnect pilot light.
4. Disconnect radio and battery wire at fuse block.
5. Remove nuts on each side of radio.
6. Remove control knobs and mounting nuts from control shafts.
7. Spring mounting brackets away from studs on sides of radio and remove radio.

1958

1. Disconnect ground cable from battery.
2. Disconnect front and rear speaker plugs from radio.
3. Disconnect antenna lead from radio.
4. Disconnect dial light wire at connector (left side of radio).
5. Disconnect foot control switch lead (if equipped) from left side of radio.
6. Disconnect radio-to-battery wire at fuse block.
7. Remove nuts from radio mounting studs.
8. Remove radio control knobs.
9. Remove two shaft housing nuts.
10. Spring two mounting brackets away from studs on sides of radio and remove radio. It is not necessary to remove electric antenna control switch (if equipped).

1959-60

1. Disconnect battery ground cable.
2. Remove glove box.
3. Remove glove box light and switch.
4. Remove air conditioning "Spot Cooler" (1959) or register (1960) if equipped.

5. Disconnect pilot light and "A" lead at two-way connector.
6. Disconnect foot control switch lead if equipped (orange wire).
7. Remove front speaker plug and rear speaker plug (if equipped) from bottom of receiver.
8. Disconnect audio power lead from audio unit (if equipped) which is located at brake pedal support.
9. Disconnect antenna lead.
10. Remove control knobs from receiver.
11. Remove two control shaft nuts, and two screws from right edge of trim plate.
12. Remove trim plate.
13. Unfasten receiver from instrument panel (2 nuts).
14. Push receiver inward from instrument panel and remove it through glove box opening.

1961-62

1. Disconnect battery ground cable.
2. On air conditioned cars, remove glove box liner.
3. Disconnect antenna lead in cable and speaker plug from radio.
4. On air conditioned cars, remove speaker grille and speaker. If rear speaker is employed, unplug speaker from speaker harness.
5. Disconnect dial lamp lead at bullet connector and power lead at main lighting junction block.
6. Remove control knobs and two nuts and washers from front of radio.
7. On 1962, remove bracket retaining nut from back of radio; on air conditioned cars remove bracket. On 1961, remove bracket retaining nut from left side of radio and bracket attaching screw from right side. On air conditioned cars, remove right radio support bracket.
8. Remove radio from car. On air conditioned cars, remove radio through speaker grille opening with push buttons facing down.

WINDSHIELD WIPER

1955-56

1. To remove wiper motor on 1954-55 first remove heater plenum chamber and radio; on 1956, remove radio only.
2. Remove retainer that holds pivot shaft arm to wiper motor pivot. Remove arms from pivot.
3. Remove motor from mounting bracket (2 screws). Lower motor until set screw that retains control cable to slide valve becomes accessible. Loosen set screw and remove cable from valve.
4. Remove vacuum hose from motor.

1957-58

The wiper motor is secured to the cowl top panel with a spacer and nut. When installing the motor, be sure the gasket is on the motor shaft end and is inserted evenly into the auxiliary drive.

To remove the wiper pivot and cable assembly, it is necessary to remove the fresh air intake grille, rubber plugs from tensioner access holes, and (on 1957) right hand fresh air duct to gain access to the auxiliary drive drum.

To install wiper pivot and cable assembly, hold tensioner in a vise and release leaf spring tension lock. Then turn tensioner enough to align the two small holes and insert a cotter pin to temporarily maintain slack. Install cables on pulleys and bend cable guide tabs to original position so they barely clear pulleys. After cables are installed on auxiliary drive drum, install tensioner assembly into cowl panel and tighten securely. Then, using a hooked tool, pull locking cotter pin out of tensioner assembly.

1959

To remove the windshield wiper cable and pivot assembly, *it is necessary to remove the glove box, radio and cowl vent grille.*

On cars with manual shift transmission, the cable end of the pivot housing must be installed from the right side of the clutch mounting bracket. Then the assembly must be rotated and at the same time entered into the mounting hole to provide clearance for the assembly.

On all models, when the tension lug on the auxiliary drive is locked in the compressed position, install the cables on the auxiliary drive. After the cables are installed, move the spring clip on the "up" position, then compress the prongs to release the tension lugs.

To locate the wiper pivots, turn ignition key to "ACC" position. Turn wiper control knob to operate wiper momentarily. Install wiper arms and blades so that they point toward right side of windshield and just contact belt moulding. Check wiper operation and make any necessary adjustments.

1960

Do not operate or test the wiper motor unless all wire connections are made. The motor may be checked for operation when it is disconnected from the cowl only when the wiring quick disconnect is connected and the motor assembly is grounded. *Under no circumstances should the motor be operated by connecting a hot lead to the motor and grounding the individual leads as damage may result.*

When removing or replacing the relay and cover assembly, care should be taken not to bend or damage the full sweep switch as the relay is adjusted and riveted to the cover.

Before attaching the motor assembly to the cowl, check its operation by connecting the wiring quick disconnect in the engine compartment to the motor wiring, turning the motor control switch and grounding the motor. *This test should be concluded by turning wiper control switch to the "off" position. This positions the motor in "park" position.*

To remove the wiper motor if the car is equipped with air conditioning, take off the glove box liner, radio speaker assembly, radio and the brace from the right defroster nozzle to the instrument panel. Remove the attaching parts and take the motor out through the speaker opening.

1961-62 Vacuum Wiper

1. If equipped with air conditioner, remove glove box liner, radio speaker and radio.
2. Disconnect vacuum hose from wiper motor.
3. Remove one screw and disconnect control cable from wiper motor.
4. Remove two bolts attaching motor to cowl.
5. On early production cars, wiper motor can be removed at this time. However, on later production models, remove 10 screws and remove cowl grille.
6. Remove nut and washer attaching auxiliary drive to motor output shaft and remove wiper motor.

1961-62 Electric Type

1. If equipped with air conditioner, remove glove box liner, radio speaker and radio.
2. Disconnect ground cable from battery.
3. Disconnect black motor feed wire at bullet connector.
4. Remove one screw and disconnect control cable from motor.
5. Remove two bolts attaching motor flange to cowl.
6. On early production cars wiper motor can be removed at this time. However, on later production models, remove 10 screws and remove cowl grille.
7. Remove nut and washer attaching auxiliary drive to motor output shaft and remove wiper motor.

Engine Section

RAISING ENGINE

1961-62 Service Note

When removing the exhaust manifold, oil pan, timing case cover or the engine front mount, the front of the engine must be raised to provide clearance. This is accomplished as follows, referring to Fig. 1A.

1. Remove engine front mount-to-front crossmember attaching nuts. On air conditioned cars, disconnect fan ring.
2. Remove threaded bolt of tool (shown in illustration) from support plate. Feed support plate through large opening in underside of front crossmember. Align hole in support plate with center hole in crossmember.
3. Attach a chain 18 to 24" long to the tool to aid in positioning the tool in and out of the crossmember.
4. Insert the threaded bolt into the support plate. Rotate the threaded bolt until it contacts the engine front mount. Raise engine until proper clearance is obtained. *When raising engine, do not allow rear of engine or engine components to contact cowl.*

Cylinder head and related parts

Cylinder block and related parts

5. When removing the timing case cover or the engine front mount, raise the engine to the desired height, then insert wood blocks between exhaust manifolds and front crossmember. Lower engine until supported on the blocks. The threaded bolt can now be lowered away from the engine front plate.

ENGINE, REPLACE

Due to variations in equipment, no attempt is made to itemize every step for an engine replacement procedure. The following recommendations are given as a guide.

1. Drain cooling system.
2. Disconnect battery cables.
3. Disconnect radiator hoses.
4. Disconnect transmission oil cooler lines (if used).
5. Disconnect exhaust pipe at front flange.
6. Remove radiator.
7. Remove hood assembly.
8. On conventional models, disconnect clutch control linkage.
9. If equipped with Hydra-Matic, disconnect transmission control linkage.
10. Disconnect accelerator control.

Fig. 1A Raising front of engine. 1961-62

Engine lubrication. V-8 engines

Fig. 1 Head tightening. 1958-62 Tighten numbered bolts first, then lettered bolts

Fig. 2 Head tightening. 1957

Fig. 3 Head tightening. 1955-56

11. Disconnect windshield wiper vacuum line.
12. Disconnect wiring from engine units including generator, starter distributor and coil.
13. Remove cable from starter terminal.
14. Disconnect flexible line from fuel pump.
15. Disconnect oil pressure gauge line at filter.
16. Disconnect propeller shaft at rear of transmission.
17. Remove two bolts attaching engine front support mounting to engine bracket.
18. Attach a lifting sling to raise power plant from above.
19. Remove rear mounting bolts and lower mounting.
20. Raise power plant to permit removal of support member.
21. Move power plant forward, raising as necessary to clear frame.
22. Reverse the foregoing procedure to install power plant.

Service Note

On V8 engines, whenever installation of a front engine mounting becomes necessary, the cap screws fastening the mounting to the frame or bracket should first be screwed finger tight, then tightened alternately, one at a time. *Do not tighten one cap screw in position independently of the other.* This is extremely important since the lower portion of the assembly would not seat evenly in the upper portion. The front mounting must be properly positioned and tightened, otherwise the mounting will not properly function as an insulator.

CYLINDER HEAD, REPLACE

1. Drain radiator and cylinder block.
2. Remove intake manifold.
3. Remove generator.
4. Disconnect exhaust pipes.
5. Remove valve cover.
6. Remove rocker arm assembly.
7. Remove push rods. Keep rods in proper sequence or otherwise tag them to be sure they will be installed in their original locations. On 1957-58 models, it will be necessary to remove the heater blower motor and core from the dash to remove the No. 8 cylinder push rods. Before removing push rods on all models, rock the rods to break the oil seal between rod and valve lifter to avoid pulling lifter from bore.
8. Remove remaining head bolts and lift off head with exhaust manifold attached.

Installation Notes—Coat a new gasket on both sides with No. 3 gasket sealer and install the gasket with the crimped side up.

After cylinder heads have been placed in position, the push rods and rocker arm assemblies should be installed and care taken to see that the push rods are properly seated in the rocker arms and valve lifters.

Cylinder head bolts should be tightened in the sequence shown in Figs. 1, 2 and 3.

On 1957 heads, tighten the bolts the first time around to 50-60 lb. ft. *except bolts 13, 14, 15 and 16 which should be tightened to 14-17 lb. ft.* Retighten the bolts in the same sequence to 60-70 lb. ft. except bolts 13, 14, 15 and 16.

On 1958-61 heads, tighten the numbered bolts in the sequence shown the first time around to 50-60 lb. ft. Tighten the lettered bolts to 14-22 lb. ft. Retighten the numbered bolts in sequence shown to 60-80 lb. ft. Then retighten the lettered bolts to 14-22 lb. ft.

VALVE ARRANGEMENT

Front to Rear

All Models ..... E-I-I-E-E-I-I-E

Fig. 5 Special tool for replacing valves and springs

ROCKER ARMS

Sludge and gum formation in the rocker arms and shafts, Fig. 4, will restrict the normal flow of oil to the rocker arms and valves. Therefore each time the assemblies are removed, they should be disassembled and cleaned.

Clean all gum and sludge formation from the inside and outside of the shafts and rocker arms. Check the fit of the rocker arms on the shafts and the valve end of the rocker arms for excessive wear. If the rocker arm radius is grooved on the valve end, do not attempt grinding; replace the part.

When assemblies are installed, make sure the rocker arms are correctly positioned to actuate the valves.

Check each push rod for a bent condition. If bent more than .020″ when checked with a dial indicator, replace the push rod. If a dial gauge is not available, at least check the rod for straightness by rolling it on a perfectly flat surface plate.

VALVES, REMOVE

With cylinder head removed as outlined previously, use a suitable valve spring compressor to compress the springs in order to take out the valve locks, Fig. 5. Then remove spring retainers, valve stem seals and valve springs. Remove burrs from valve stem lock grooves to prevent damage to valve guides, and slide valves from heads.

Place valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to the original guide holes.

Fig. 4 Layout of rocker arm parts. 1955-56

Fig. 5A Checking installed height of valve spring

Fig. 7 Tool for removing stuck valve lifter

VALVE GUIDES

Check valve stem-to-guide clearance, using a $\frac{1}{16}''$ wide strip of .005″ brass shim stock on a "no-go" basis. Bend the end of the shim and hang it in the end of the valve guide. Shim should not extend more than ¼″ into the guide. If valve stem will enter guide, clearance is excessive and valve and guide should be replaced to prevent excessive oil consumption and improper seating of valves.

Unless a special installing tool is available for guides, before removing a guide, measure the distance it sticks out of the valve port with a steel scale. Then drive out the old guide and install the new one to the measured depth.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 5A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 6 Valve spring testing fixture

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}''$ to $\frac{5}{64}''$, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valve springs, wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching,

Fig. 8 Hydraulic valve lifter

Fig. 9 Valve timing for No. 6 cylinder

Fig. 10 Correct assembly of pistons and rods. 1955-56 V8

which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, Fig. 6, if one is available, and according to the specifications given in the *Valve Specifications* chart.

If a spring tester is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications with 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

VALVES, GRIND

Valve seats should be cut so there is $\frac{1}{32}$" from the outer edge of the seat to the edge of the flange on the valve head to allow heat to escape and to provide maximum life for newly ground valves.

Cars operated at moderate or slow speeds in city driving should have a valve seat width of $\frac{3}{64}$" to $\frac{1}{16}$". For cars driven a great deal at high speeds the seat width should be $\frac{1}{16}$" to $\frac{3}{32}$" to assure adequate cooling.

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. Both tests are necessary to prove that a proper seat is being obtained.

VALVE LIFTERS

See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Place one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

To remove valve lifters, take off successively the intake manifold, engine push rod cover, valve cover, rocker arm shaft assembly, push rods and remove valve lifters, Fig. 7.

Valve lifters in production engines may be one of four sizes: standard, .001, .002 or .003 in. oversize. It is important when replacing one or more lifters that the proper size lifter be ordered. An identification numeral is etched on all lifter bodies except standard. The cylinder block is marked for lifter size on the rail under the push rod cover. Valve lifters .005 in. oversize are available for service replacement.

When a lifter has been in service for a long time, the body bore above the plunger may be caked with hard carbon so that the plunger cannot be removed easily. When this condition exists, submerge the lifter in a suitable carbon softener for a time and then remove the carbon with a stiff bristle brush.

When the lifter is disassembled, use extreme care to avoid nicking or otherwise damaging the body and plunger through contact with other parts. Keep the parts of one lifter separate from all others so that parts will not be interchanged during assembly.

Plungers are not interchangeable because they are selectively fitted to the bodies at the factory, Fig. 8.

If plunger and body appear satisfactory blow off with air to remove all particles of dirt. Install the plunger in the body without other parts and check for free movement. A simple test is to be sure that the plunger will drop of its own weight in the body.

TIMING CASE COVER

1961-62 Service Note

See procedure for raising front of engine as described at the beginning of the engine text matter.

1. To remove front cover, drain cooling system and disconnect lower radiator hose and heater hose from front cover.
2. Disconnect generator link at generator.
3. Remove oil pan.
4. Remove two bolts attaching front engine mount to frame.
5. Support engine so that engine mount will clear frame cross member.
6. Remove radiator.
7. Remove fan blades and pulley.
8. Remove crankshaft pulley.
9. Crank engine until distributor rotor points to No. 3 or No. 7 firing position; then remove fuel pump.
10. Unfasten and remove front cover.
11. Reverse the operations to install the cover. However, always install a new front oil seal. The front cover attaching bolts should be dipped in a suitable sealer and torqued to 24-40 lb. ft. One side of the fuel pump gasket should be coated with gasket cement to hold it in place during its installation.

Fig. 11 Assembly of piston to rod. 1957-62

TIMING CHAIN

Place the chain over the sprockets so that when the camshaft sprocket and fuel pump eccentric are bolted to the camshaft hub, the timing marks on both sprockets are facing each other in line with the center of both the camshaft and crankshaft, Fig. 9. The fuel pump eccentric must be assembled with the cupped side out.

CAMSHAFT, REPLACE

1. To remove the camshaft, remove valve lifters.
2. Remove distributor.
3. Remove engine front cover.
4. Remove camshaft thrust plunger, fuel pump eccentric, camshaft sprocket and timing chain.
5. Remove camshaft by carefully sliding it out from front of engine.
6. To install, reverse the above sequence of operations. Lubricate the end of the camshaft thrust plunger with suitable seal lubricant. Set valve timing, ignition timing, adjust carburetor idle and check throttle linkage.

PISTONS & RODS, REMOVE

After removing the connecting rod cap, push the rod and piston out through the cylinder bore, being careful to keep the rod in alignment to clear the crankshaft. The internal crankcase clearances are very limited and extreme care must be

taken not to damage parts. After removing the piston assembly, reinstall the bearing cap. Remove seven other pistons in the same manner.

PISTON & ROD, ASSEMBLE

1955-56

On 1, 3, 5, 7 pistons, assemble the connecting rod with the machined surface of the bearing face on the same side as the "F" marks, Fig. 10. On 2, 4, 6, 8 pistons, assemble rods with machined surface having two bosses placed on same side as letter "F."

1957-62

Lubricate the piston pin hole and piston pin to facilitate installation of pin, then position the connecting rod with its respective piston as shown in Fig. 11.

PISTONS

For checking sizes of stock pistons, measurements should be taken with micrometer calipers across the high point of the piston skirt contour, which is across the piston pin support ribs on the piston skirt.

Before any attempt is made to fit new pistons, cylinder bores should be carefully measured, and refinished. Cylinders that are not badly scored but need a "cleaning up" to bring them within satisfactory working limits may be reconditioned with a hone.

A good job should show measurements of not more than .0005" out-of-round or taper. If cylinders are scored badly or out-of-round excessively, they should be bored first with a reliable boring tool and then polished with a hone.

When fitting pistons, use feeler stock of the thickness given in the *Piston & Ring* table. The feeler should be about ½" wide and long enough to extend down into the bore for the full length of the piston. Insert the piston into the bore upside down and place the feeler stock between the piston and the cylinder wall on the high point of the piston contour. Hook the feeler to a spring scale and withdraw the feeler by pulling it out of the cylinder with the scale. The piston is fitted properly if the amount of pounds pull registered on the scale comes within the limits given in the *Piston & Ring* table.

PISTON RINGS

Piston rings are available in standard sizes and the following inch oversizes: .010. .020 and .030.

When installing a new set of rings without reconditioning the cylinder bores, always remove the top ridge of the bore with a reliable ridge reamer. Care must be taken not to cut below the top of the upper ring position in the bore. Always cut the ridge before removing the piston assemblies, keeping the tops of the pistons covered to prevent cuttings from reaching bearings, crankshaft, timing case, etc.

Fig. 12 Checking bearing clearance with Plastigage

New rings must be fitted with end gaps and groove clearances according to the specifications given in the *Piston & Ring* table. Ring grooves must be clean and free from carbon and must show no perceptible wear.

Install rings according to the instructions which are usually contained in the ring package. When assembled on the pistons, the gaps should be staggered around the circumference of the piston but with no gaps over the piston pin.

PISTON PINS

Piston pins are available in standard, .001" and .003" oversizes. If necessary, reaming and honing of the piston pin hole for the installation of oversize pins are satisfactory. The fit of the pin in the piston should be a tight hand push. If considerable hand pressure is required, the pin may be tapped in place with a hammer and brass drift.

It is very important that both the pin and piston pin hole be clean and free from oil. When assembling the rods to the pistons, follow directions shown in Figs. 10 and 11.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves. The clearance between the rod bearing and crankshaft can be measured with Plastigage gauge as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall the cap and tighten to the torque value given in the *Engine Tightening Specifications* table.
4. Remove the bearing cap and determine the clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage envelope. The number within the graduation on the envelope indicates the clearance in thousandths of an inch, Fig. 12. If this clearance is greater than specified, replace the bearing.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed.

Be sure to remove cardboard. To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening Data* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not

Fig. 13 Ignition details. 1955

Fig. 14 Ignition details 1956-62

bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN

1955-58

To remove the oil pan, remove the starting motor on engines up to 1955 or merely loosen it on 1956-58 models.

Disconnect exhaust crossover pipe. Disconnect idler arm support from frame. Unfasten and remove pan.

1959-60

1. Position No. 1 piston on bottom of stroke. This moves crankshaft counterweight out of the way to aid in the pan's removal.
2. Disconnect battery cable.
3. If equipped with single exhaust system, remove exhaust crossover pipe.
4. Disconnect idler arm support from frame.
5. Remove starter and lower flywheel housing.
6. Drain and remove oil pan. *Holes are provided in the frame crossmember for access to the four front oil pan bolts.*

1961-62

The oil pan is removed in the same manner as outlined for 1960 models. However, it is necessary to raise the engine, the procedure for which is described at the beginning of the engine text matter.

OIL PUMP

The positive gear type oil pump is attached to the rear main bearing cap by three bolts and can be removed without disturbing any of the drive mechanism.

To disassemble the pump, release lock wire and remove screen. Take off the oil screen shroud and remove the snap ring from the extension shaft coupling. Remove the oil pump cover and take out the gears. Remove oil pressure regulator nut, spring and valve.

RADIATOR, REPLACE

1955-58

To remove the radiator, drain the complete cooling system. Disconnect upper and lower radiator hoses. Disconnect horn wires and remove horns.

If car is equipped with Jetaway transmission, disconnect and cap oil cooler lines. Disconnect radiator shroud and position away from radiator.

Remove upper radiator baffle. Remove screws from radiator flange (both sides). Position fan blades to clear radiator lower outlet and remove radiator.

1959-62

1. Drain cooling system and disconnect upper and lower hoses. If equipped with Hydra-Matic, disconnect and cap oil cooler lines.
2. Remove fan upper support.
3. Unfasten radiator from flange (6 screws). If equipped with air conditioning, position fan ring away from radiator.
4. Position fan blades to clear radiator lower outlet and remove radiator.

WATER PUMP, REPLACE

Remove fan and fan pulley. Remove six water pump attaching bolts and lift off pump.

When reinstalling the pump, one side of the pump bearing housing gasket should be coated with gasket cement. The four bearing housing bolt threads should be dipped in a suitable sealer.

WATER PUMP REPAIRS

The water pump double row bearing has one large groove in the center and two smaller grooves toward one end. The end with the two smaller grooves must always be assembled into the pump housing first. This end of the bearing shaft will then be at the impeller end of the pump.

To assemble the pump, press the seal into the housing. Press the bearing into the housing until the bearing seats on shoulder in housing. Install the bearing retainer spring at the front end of the housing. Press the bearing shaft through the impeller until the bottom edge of the vanes are $\frac{13}{16}$" from the machined face at edge of housing. If the fan hub was removed, press the hub on the shaft.

DISTRIBUTOR, REPLACE

1. Disconnect primary wire from distributor and disconnect pipe from vacuum control unit.
2. Remove distributor cap.
3. Crank engine until distributor rotor is in position to fire No. 1 cylinder and the timing mark (see *Tune Up Chart*) is aligned with the timing indicator.
4. Remove distributor clamp and lift the distributor out of the crankcase.

Installation, All Models

Before installation of either a new or repaired distributor apply a few drops of engine oil to the drain hole near the lower and of the housing and apply oil to the oiler on the housing. Rotate the distributor shaft several times by hand

Fig. 15 Ignition timing marks. Left view is for 1955-56 and first 15,000 cars for 1957. Right view is used on later 1957 and 1960-62 models.

to distribute the oil and to make sure that the shaft turns freely.

1. Check to make sure that the timing mark is aligned with the timing indicator with No. 1 piston on the compression stroke in position to fire.
2. Place a new seal or gasket on distributor housing.
3. Rotate distributor cam until rotor is in position to fire No. 1 cylinder, Figs. 13 and 14.
4. Rotate oil pump shaft with screwdriver to align slot in shaft with tongue on lower end of distributor shaft.
5. Install distributor in crankcase.
6. Install distributor clamp and bolt with lockwasher, leaving bolt just loose enough to permit movement of distributor.
7. Rotate distributor housing until breaker points just start to open and tighten clamp bolt. This will permit starting engine for setting timing.
8. Connect pipe to vacuum control and primary wire to terminal stud.
9. Install distributor cap. If spark plug wires are disconnected from cap make certain that wires are connected in accordance with firing order, Figs. 13 and 14.
10. Check and set ignition timing as given below.

IGNITION TIMING

The timing marks are located on the rim of the crankshaft pulley in the form of a slot on 1953-56 and the first 15,000 cars on 1957 models. As shown in Fig. 15, later 1957 and 1960-61 models have three slots.

For 1958-59 there are two slots, the first to come under the pointer is 5° before top dead center and the second slot is T.D.C.

The slow idle method of setting ignition timing, formerly recommended, should not be used. The correct method of setting the timing is as follows:

1. *Disconnect distributor vacuum advance line at the carburetor and close the carburetor fitting with a piece of tape.*
2. Connect a tachometer and set the carburetor throttle adjustment so the engine runs at 850 RPM.
3. Set the timing at 5° before top dead center. This is the normal setting. If a tuned engine detonates with this setting the cause is low octane fuel or carbon build-up in the combustion chambers. If these factors are not corrected the timing should be set at 2½° before top dead center at 850 RPM. In some cases where fuel octane is good or the engine is clean or the car is operated at higher altitudes, the timing can be set at 7½° before top dead center at 850 RPM without detonation and with some advantage in performance.
4. Remove the tape from the carburetor fitting, connect the distributor vacuum line to the carburetor and reset the slow idle speed.

STARTER, REPLACE

1956-62

Disconnect battery cable at junction block and solenoid wire (purple) from chassis wiring harness. Raise car and remove engine filler plate (if used). On cars with dual exhaust, disconnect exhaust pipe at manifold. Unfasten starter from flywheel housing and remove motor while sliding battery cable loom through sleeve.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Never use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

ROCHESTER CARBURETOR ADJUSTMENTS

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1959-62, Fig. 1A

1. Insert a ¼″ rod in gauge pin holes provided in frame side rail.
2. Remove clevis pin from upper end of rod "A". The overcenter springs will hold bottom of rod against gauge pin.
3. Loosen lock and adjusting nuts on rod "B" until rod is free of tension.
4. Turn back floor mat and adjust pedal stop screw until top of pedal pad is 8″ from floor pan. After linkage is connected, pedal height should be 8¼″ with spring load applied.
5. Adjust upper clevis on rod "A" until gauge pin is free in frame hole, after rod "A" is connected to pedal bellcrank. Install clevis pin and tighten lock nut.
6. Adjust rod "B" until 1 to 1¼″ free pedal travel is obtained. Tighten lock nut and remove gauge pin.

1955-58

To adjust the free travel of the clutch pedal, loosen the lock nut on the adjustable rod and turn the adjusting nut in the desired direction to obtain from 1 to 1¼ inches free travel.

Fig. 1A Clutch linkage. 1959-62

Fig. 2 Synchromesh transmission. All Models

CLUTCH, REPLACE

1. Remove transmission as outlined further on. Then remove transmission bearing retainer sleeve.
2. Remove left engine filler plate, engine breather pipe, and right and left rear lower flywheel housing bolts.
3. Remove clutch pedal return spring and disconnect adjustable rod at the yoke.
4. Install engine support bar if one is available. If not, support rear of engine with a suitable jack.
5. Remove engine rear mount bolts at clutch housing and remove frame crossmember by removing three bolts at each end.
6. Remove bolts securing clutch housing to flywheel housing, and remove clutch housing and release yoke.
7. Mark flywheel and clutch cover for correct positioning at reassembly.
8. Remove clutch from flywheel, Fig. 1.
9. To install, reverse sequence of removal operations. Use an old transmission mainshaft to align clutch disc while tightening clutch to flywheel. Lubricate clutch shaft pilot bearing and bearing surface of release levers. Adjust transmission shaft linkage and adjust clutch pedal free travel. Lubricate clutch release bearing.

Fig. 1 Section through clutch. Typical of all models

TRANSMISSION, REPLACE

1955-56

After raising the car, drain the transmission and disconnect the manual control rods and speedometer cable at transmission. Detach drive shaft at rear universal joint and slide shaft from transmission Remove bolts holding transmission to the clutch housing and slide transmission out.

1957-62

1. Drain transmission and disconnect control rods and speedometer cable at transmission.
2. Remove propeller shaft.
3. Remove transmission-to-clutch housing bolts and slide the transmission rearward until the main drive shaft clears the clutch housing. Lower the transmission.
4. To install the transmission, apply Lubriplate to the pilot and the first 1″ of slines on the main drive shaft. Reverse the sequence of removal operations, align the propeller shaft, and adjust transmission shift linkage.

TRANSMISSION REPAIRS

1. Thoroughly clean all dirt from exterior of transmission to avoid getting dirt into bearings when transmission is opened, Figs. 2, 3.
2. Remove transmission cover and gasket, toggle spring, spring clip and spring extension.

Fig. 3 Synchromesh transmission

3. Remove speedometer driven gear, then remove rear bearing retainer and gasket.
4. Place transmission in second gear, move mainshaft back until rear bearing is clear of case, and disengage shift yoke from synchronizer. Then lift front end of mainshaft enough to remove synchronizer from shaft. Note that the counterbored end of the synchronizer must face the second speed gear when replaced.
5. Remove snap ring holding second speed gear to mainshaft. Remove thrust washer after lining up small wire spacer ring installed in bottom of snap ring groove with thrust washer key, then remove second speed gear from mainshaft.
6. Remove snap ring holding low and reverse gear to mainshaft.
7. Slide low and reverse gear off mainshaft while pulling shaft out through rear of transmission case.
8. Place transmission levers in neutral and remove set screws holding shifter yokes and levers to their respective shafts. NOTE: Each yoke shaft is in neutral position when the notch for the shifter lever is directly above the selector shaft.
9. Slide shift lever and interlock away from second and high yoke shaft, then remove interlock retainer from groove in right end of selector shaft.
10. Remove outer shift lever and lock washer from left end of selector shaft and, after making sure transmission is still in neutral, depress inner selector lever and drive the shaft out through the right side of the transmission, using a soft hammer. NOTE: The welch plug in right side of case will be driven out by the shaft. Do not allow shift levers and interlock to drop into case.
11. Push second and high speed yoke shaft out through front of case, taking care to prevent poppet ball and spring from flying out. Remove shift yoke, ball and spring.
12. Taking care to prevent poppet ball and spring from flying out, push low and reverse yoke shaft out through rear of case. Remove poppet ball, spring and low and reverse interlock pin.
13. Drive countershaft lock pin into the shaft, then drive shaft out through rear end of case, using a suitable tool to hold needle bearings and washers in place. Allow cluster gear to rest on bottom of case.
14. Remove snap ring from main drive gear bearing and tap drive gear and bearing toward rear of transmission to remove.
15. Carefully raise cluster gear out of case so that related parts remain in gear.
16. Remove transmission outer selector lever, lock washer and nut; then remove inner lever and shaft, spring washer, flat washer, and oil seal from case.
17. Drive reverse idler gear shaft lock pin into the shaft, then remove shaft, gear and thrust washers.

Assembly Notes — Reverse the order of the foregoing procedure to assemble the transmission, observing the following:

Install the reverse idler gear so that the chamfered teeth is at the rear of the case. The idler gear shaft is ground slightly larger at one end in order to form a positive seal at the rear end of the transmission case. Make sure that this end of the shaft is at the rear when replaced and that the small hole in the opposite end lines up with the lock pin hole in the case. Install a new lock pin coated with white lead or other sealing compound to prevent leaks. Drive lock pin 1″ below surface of boss on case.

When installing the cluster gear and related parts, note that a small diameter bronze washer and a steel washer are used at the rear of the gear (bronze washer next to gear) and a larger bronze washer (only) is used at the front. When countershaft is installed, install a new lock pin coated with white lead or other suitable sealing compound to prevent leaks. Drive pin flush with surface of transmission case.

After shift yoke shafts are installed, install a new welch plug coated with white lead or other sealing compound in right side of transmission case.

After installing second speed gear on mainshaft and, after lining up the small wire spacer ring in bottom of mainshaft snap ring groove with spline which is machined *part way* onto the ground second speed gear bearing surface, install second speed gear thrust washer and snap ring. Note that one spline is machined the entire length of the second speed gear bearing surface on the mainshaft. This full spline is for lubrication purposes and should not be obstructed by the thrust washer key.

GEARSHIFT, ADJUST

1955-56

Two adjustments are required to properly position the hand control lever with respect to the steering wheel. The procedure is as follows:

Set the transmission outer shift lever in neutral. Adjust the clevis to obtain a dimension of 1¼″ on 1953, 2″ on 1954, and 2$\frac{11}{16}$″ on 1955-56 (horizontal) between the steering wheel centerline to the centerline of the shift lever knob. With transmission outer selector lever against rear stop, and hand control lever knob resting in neutral position, adjust the clevis on this rod so that the clevis pin will easily enter the hole in the lever.

Remove the clevis pin connecting the outer selector lever to the cross shift lever, lengthen the clevis by 3 full turns and replace the pin. This gives the proper vertical adjustment between the steering wheel and shift lever knob.

1957-62, Fig. 4

To adjust the shift lever position, set the transmission shift lever in second gear position. Disconnect shift rod from steering column lower shift lever at the clevis. Hold the steering column lower shift lever against its stop in the mast jacket. Adjust the shift rod clevis so the pin enters freely the clevis and lever. Then remove the clevis pin and shorten the rod by 3 full turns (5½ on 1959-62)

of the clevis. Secure the adjustment.

To adjust the cross shift linkage, disconnect the cross shift rod from the cross shift lever. With the transmission selector held rearward against its stop, adjust the cross shift rod clevis so that its pin will freely enter the hole in the lever while holding the cross shift lever rearward to take up the lash. Then remove the clevis pin and lengthen the rod by three (5 on 1959-61) full turns of the clevis. Secure the adjustment.

HYDRA-MATIC DRIVE

Hydramatic, Replace, 1955

1. To remove the hydramatic, raise the car off the floor and drain the oil from the transmission.
2. Disconnect side pan at rear and drop out of place in order to remove starter. Starter wires should be identified so that they can be reinstalled properly.
3. Remove the exhaust pipe and crankcase ventilator brackets from the lower flywheel housing and then remove housing (attached by 8 cap screws).
4. Remove flywheel housing pan.
5. Remove ⅛ in. hex head plug from torus cover to drain oil.
6. Disconnect propeller shaft at rear universal joint and slide rearward away from transmission.
7. Disconnect speedometer cable at transmission.
8. Remove transmission fluid filler tube from transmission oil pan.
9. Disconnect manual rod from transmission lever.
10. Remove throttle rod lever.
11. Remove 30 torus cover-to-flywheel attaching screws and lockwashers.
12. Support the engine at the rear with a suitable support bar or other available means.
13. Remove two bolts, engine mount-to-frame cross member (left side only). Remove two cap screws from engine mount-to-flywheel housing (right side only).
14. Remove three bolts from each end of cross member-to-frame.
15. Lift engine approximately ½ in. and remove frame cross member.
16. Lower engine just enough to remove transmission-to-bell housing upper screws (approximately 1½ in.). *Do not lower engine more than 1½ in. to remove upper cap screws unless upper radiator hose and exhaust pipe-to-manifold connection are loosened.*
17. Remove the two remaining transmission-to-bell housing cap screws.
18. Remove transmission assembly by moving it toward the rear of the car, and at the same time lowering assembly to floor. *To prevent the end of the mainshaft from striking the flywheel-to-crankshaft bolts when lowering the transmission, be sure to turn the flywheel so the end of the mainshaft passes between the two bolts.*
19. Reverse the foregoing procedure to install the transmission and adjust the control linkage as outlined below.

Fig. 4 Synchromesh transmission linkage. 1957-62

Hydramatic, Replace, 1956-60

1. Disconnect battery.
2. Remove trans. oil filler tube.
3. Drain transmission.
4. Disconnect speedometer cable.
5. Remove linkage from transmission levers. *Remove throttle lever.*
6. Remove crankcase breather tube.
7. On 1956 models, remove propeller shaft. On 1957-60 models, scribe a line from one of the propeller shaft center bearing support-to-frame bolts on the frame member for later center bearing support alignment. Remove propeller shaft center bearing support bolts and shims. *Identify shims so the same total thickness of shims can be reinstalled.* Disconnect the two "U" bolts at transmission companion flange. Raise center bearing so it will clear frame member and slide front propeller shaft and bearing approximately 2″ to rear of slip joint (the bearing mounting plate will rest on frame and keep propeller shaft from dropping down).
8. Disconnect left-hand exhaust pipe (if dual exhaust equipped).
9. Remove starter.
10. Support transmission with jack.
11. Raise engine enough to relieve weight from rear engine mounts. Unfasten engine mount from cross member.
12. Remove cross member.
13. Remove lower flywheel housing.
14. Drain torus.
15. Lower engine not more than 1½″ to permit removal of the two upper flywheel housing to block bolts.
16. Disconnect oil cooler hoses from lines and *cap lines immediately.*
17. Remove four flex plate-to-flywheel attaching bolts.
18. Remove remaining flywheel housing-to-block bolts.
19. Move transmission rearward approximately ¾″ to clear dowels and lower transmission from car.
20. Reverse above procedure to install. Torque flex plate-to-flywheel attaching nuts 20-25 lb. ft. Torque oil pan drain plug 35-45 lb. ft. Torque throttle lever 10-12 lb. ft.

1961-62

1. Disconnect transmission vent pipe from rear of right-hand exhaust manifold.
2. Raise car and remove oil filler pipe from transmission and drain fluid.
3. Disconnect speedometer cable and shift levers from transmission.
4. Remove propeller shaft.
5. Disconnect exhaust pipe bracket from transmission rear housing.
6. Support rear of engine.
7. Support transmission with transmission lift.
8. Raise engine enough to relieve weight from rear engine mounts and remove bolts attaching mounts to crossmember.
9. Remove crossmember.
10. Lower engine enough to gain access to upper transmission attaching bolts.
11. Disconnect oil cooler lines and cap lines immediately.
12. Pry vent pipe from transmission case.
13. Remove remaining transmission attaching bolts.
14. Position exhaust pipe bracket to clear transmission output shaft, then move transmission rearward about 1½″ to disengage input shaft from damper hub.
15. Lower transmission from car.
16. Reverse removal operations to install transmission and adjust shift linkage.

Manual Linkage, Adjust 1955-60

Set the transmission manual lever in neutral detent position. Disconnect manual rod from lower shift lever. Hold lower shift lever upward so selector lever is positioned against stop in upper steering column. Adjust manual rod end so pin will enter approximately ⅛″ into lower shift lever bushing with selector lever against stop. On 1959-60 models, lengthen clevis 2½ turns. Tighten clevis lock nut and connect manual rod to lower shift lever.

Throttle Linkage, Adjust All Models

Before making any checks or adjustments of the linkage, check the performance of the engine. The transmission is often blamed for poor operation of the vehicle when the engine is not tuned to deliver maximum power.

There are so many linkage variations and intricate hook-ups that it is impractical to illustrate and go into specific procedures for each one. However, there are only two things to remember when it becomes necessary to adjust the throttle linkage.

1. Throttle linkage must be adjusted so that when the carburetor throttle valves are fully closed (hot idle) the transmission throttle valve lever must be all the way toward the rear of the transmission against the internal stop.
2. In order to assure kickdown operation, the accelerator pedal linkage must be adjusted so that when it is fully depressed, the carburetor throttle valves are in wide open position.

The most obvious symptom of mis-

adjusted throttle linkage is either the absence of a 4-3 (3-2 on 1961-62) kickdown or a kickdown which takes place before full throttle is reached. Lengthening or shortening the lower throttle rod to the transmission controls kickdown to a great extent. Before adjusting the lower throttle rod, however, the proper functioning of the upper or carburetor throttle rod must be ascertained. In general, the following procedure should be followed:

When There is No Kickdown:

1. Disconnect lower throttle rod at transmission.
2. With engine shut off, depress the accelerator pedal down to the floor. With the pedal in this position, the carburetor throttle valves should be wide open. If not, check for obstructions such as a lumpy floor mat under the pedal or misaligned linkage. It may be that the length of the upper throttle rods have to be changed through adjustment to obtain wide open throttle at the carburetor.
3. While holding the fast idle cam (of carburetor) in the "off" position, release the accelerator pedal slowly. The pedal return spring should bring the throttle back to the hot idle position. If it doesn't, make the necessary corrections.
4. Reconnect the throttle rod at the transmission and adjust by shortening a turn at a time between road tests until kickdown is obtained.

Kickdown Occurs Before Wide Open Throttle Is Reached:

1. Follow Steps 1, 2 and 3 as outlined above.
2. Reconnect lower throttle rod at transmission and adjust by lengthening a turn at a time between road tests until the transmission kicks down at the desired throttle position.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE, 1955-56

In these axles, Fig. 1, the companion flange is fastened to the pinion stem with a special nut which seats directly on a counterbore in the flange. The nut is retained by staking the end of the pinion stem into two slots milled on top of the nut.

The drive pinion is mounted on preloaded taper roller bearings. Adjustment of the pinion along its axis is obtained by shims placed between the rear bearing outer race and a shoulder in the carrier. Adjustment of preload of the two bearings is obtained by tightening the companion flange nut which compresses a sleeve over the pinion stem between the bearings. Both bearing outer races are pressed into the carrier, the rear race against pinion adjusting shims, the front race against the shoulder in the carrier. The rear bearing inner race is pressed onto the pinion stem to a shoulder at the pinion end. The front bearing is a light press to a close sliding fit on the pinion stem.

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, is given in the *Rear Axle Chapter*.

Pinion & Bearings, Replace

After removing the differential unit from the carrier, unscrew the pinion flange retaining nut and pull off the

Fig. 1 Rear axle, 1955-56

Fig. 2 Measuring pinion bearing preload with a torque wrench

flange. Press the pinion out of the front bearing and through the rear end of the carrier. The rear bearing cone and bearing spacer will come out with the pinion. The bearings may then be removed and installed with suitable pulling equipment.
